CORRELATION BETWEEN HEMATOLOGICAL PROFILE, ERYTHROCYTE SEDIMENTATION RATE, AND HISTOLOGICAL TYPE OF DIGESTIVE SPINAL METASTASIS (Abstract). **The objective** is to analyze possible correlations between histological types, hematological tests and erythrocyte sedimentation rate that can be identified in vertebral metastases secondary to digestive cancers. **Materials and methods:** The present study is a retrospective observational research of 27 patients with spinal metastases identified in the Prof. Dr. N. Oblu Emergency Clinical Hospital in Iași over a period of 8 years (2014-2021). For each patient, were recorded: patient demographics, including age and gender; tumor histology; hematological analyses (erythrocyte count, hemoglobin, hematocrit) and erythrocyte sedimentation rate. **Results:** The mean age of the group was 64.3 years. The male: female ratio was 19: 8=2.375. The most frequent histological subtypes of vertebral metastases were colonic adenocarcinomas (CAC) (n=12 cases; 44.4%,) and hepatocellular carcinomas (HCC) (n=6 cases; 22.2%), followed by squamous cell carcinomas (SCC) of oral and rectal origin (n=3 cases; 11.1%), rectal adenocarcinomas (RAC) (n=2 cases; 7.4%), and cholangiocarcinomas (CC) (n=2 cases; 7.4%). RAC cases presented the lowest erythrocyte counts (2.62 $\times 10^6$/mL), while neuroendocrine carcinoma (NEC) of the small intestine showed the highest mean values (4.20 $\times 10^6$/mL). RAC cases presented the lowest hemoglobin levels (8.3 g/dL), while CC and NEC (small intestine) demonstrated relatively higher averages (>11 g/dL). RAC cases demonstrated the lowest mean hematocrit (~31%), while oral cavity SCC presented the highest mean values (~38%). Spinal metastases of CAC, HCC, or CC showed intermediate levels (36-37%). Spinal metastases of RAC cases presented with the highest mean ESR values (~60-70 mm/h), and NEC of small intestine showed the lowest averages (~25 mm/h). **Conclusions:** Hematological profile and erythrocytes sedimentation rate (ESR) in spinal metastases of digestive origin show reproducible, histology-specific patterns: rectal primaries cluster with profound iron-deficiency anemia and high ESR; colon adenocarcinoma and hepatocellular carcinoma show intermediate anemia with variable inflammation; cholangiocarcinoma and neuroendocrine tumors of small intestine often pre-

serve hematological parameters with lower ESR. Integrating RBC/Hb/Ht with ESR enhances clinical triage, informs supportive care, and may improve prognostication when embedded in multivariable models. **Keywords**: SPINAL METASTASES, DIGESTIVE SYSTEM CANCER, HEMATOLOGICAL PROFILE, ERYTHROCYTE SEDIMENTATION RATE.

INTRODUCTION

Bone metastases are one of the most common complications of advanced neoplastic disease, with a significant impact on the quality of life and prognosis of patients. Although the most well-known sources of spinal bone dissemination are breast, prostate, and lung cancers (1), tumors of digestive origin can also generate vertebral metastases (2), sometimes clinically underestimated.

The spine is the favorite site of bone metastases originating from digestive cancers (3), as the rich venous vascularization and lack of valves in the vertebral plexuses (Batson plexus) facilitate hematogenous dissemination of tumor cells (4).

There are studies that have shown that certain laboratory tests can be useful in the early detection of bone metastases. Some authors have reported that elevated serum calcium (>2.54 mmol/L) and alkaline phosphatase (>116 U/L), but lower values of hemoglobin (<37.5 g/L) are risk factors for developing bone metastases of bladder cancer (5). Some other researchers reported that serum levels of prostate specific antigen (PSA), alkaline phosphatase (ALP), bone sialoprotein (BSP), collagen type I pyridine crosslinking peptide (ICTP) are increased in patients with bone metastases, and their combined detection could improve their positive predictive value (6).

The objective of this study is to analyze possible correlations between histological types, hematological tests (number of erythrocytes/mL, Hb, Ht), and erythrocyte sedimentation rate that can be identified in vertebral metastases secondary to digestive cancers.

MATERIAL AND METHOD

Study design. The present study is a retrospective observational research of patients with spinal metastases identified in the Prof. Dr. N. Oblu Emergency Clinical Hospital in Iași over a period of 8 years (2014-2021). We retrieved and examined eligible cases through the hospital case management system, using the disease code, which was standardized according to the International Classification of Diseases, Tenth Revision (ICD-10), and patient information was obtained by analyzing the medical records of hospitalized patients.

We identified a sample of 27 hospitalized patients, diagnosed and surgically treated for vertebral metastases secondary to digestive system cancer. For each patient, the following indicators were recorded: patient demographics, including age and gender; tumor histology; hematological analyses (erythrocyte count, hemoglobin, hematocrit) and erythrocyte sedimentation rate.

The inclusion criteria were: (1) adult patients (≥18 years old); (2) Diagnosis of spinal metastasis of a histologically confirmed digestive cancer; (3) availability of a minimum set of biological data (erythrocytes, hemoglobin, hematocrit, and ESR) that could be analyzed retrospectively.

Exclusion criteria were: (1) patients younger than 18 years; (2) patients with other spinal diseases, tumoral or non-tumoral.

Statistical analysis. The data were entered into a digital file and processed using

Python statistical software. The following methods were applied: descriptive statistics (mean); Kruskal-Wallis test for comparing groups according to non-parametric variables; graphical representations: (pie chart and bar chart).

Ethics. The data was anonymized before analysis. The study was approved by the Ethics Committee of the Prof. Dr. N. Oblu Emergency Clinical Hospital, Iași, and by the Ethics Committee of the Grigore T. Popa University of Medicine and Pharmacy, Iași. The research complies with the ethical principles of the Declaration of Helsinki and national regulations on the processing of personal data for research purposes. Each patient/guardian gave informed consent to obtain samples and their use for study purposes.

RESULTS

Demographic data. The study group included 27 patients with spinal metastases originating from a primary tumor of the digestive system. The male: female ratio was 19: 8=2.375, in favor of the male gender. The mean age of the group was 64.3 years.

Histological types of spinal metastases in the present series. In the analyzed cohort (fig. 1), the most frequent histological subtypes of vertebral metastases were colonic adenocarcinomas (n=12 cases; 44.4%) (fig. 2) and hepatocellular carcinomas (n=6 cases; 22.2%). These were followed by squamous cell carcinomas of oral and rectal origin (n=3 cases; 11.1%), rectal adenocarcinomas (n=2 cases; 7.4%) (fig. 3), and cholangiocarcinomas (n=2 cases; 7.4%) (Fig. 4). Single cases were represented by a neuroendocrine tumor of the small intestine and by a gastric adenocarcinoma (n=1 case each; 3.7%) (fig. 5).

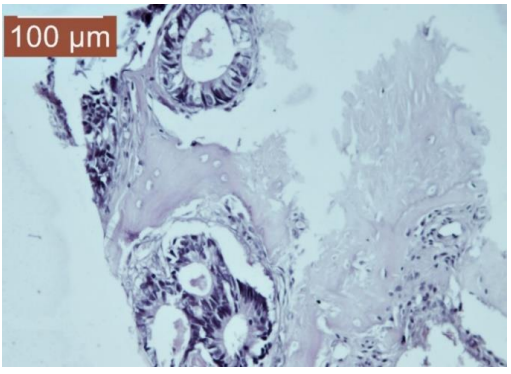

Fig. 2. Microscopic aspects: spinal metastasis originating from a moderately differentiated colonic adenocarcinoma (HE, x20).

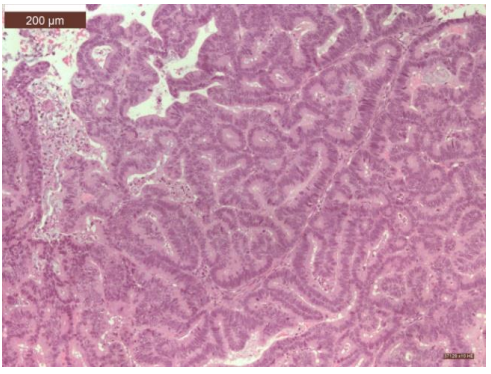

Fig. 3. Microscopic aspects: spinal metastasis originating from a moderately differentiated rectal adenocarcinoma (HE, x10).

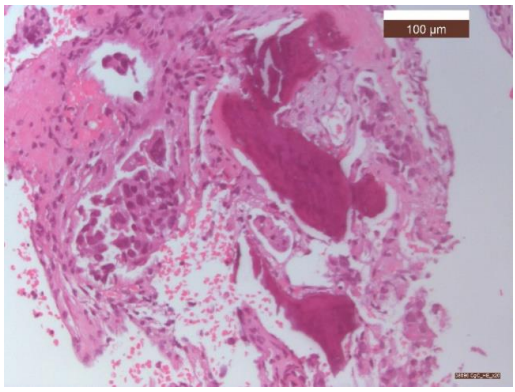

Fig. 4. Microscopic aspects: spinal metastasis of poorly differentiated cholangiocarcinoma (HE, x20).

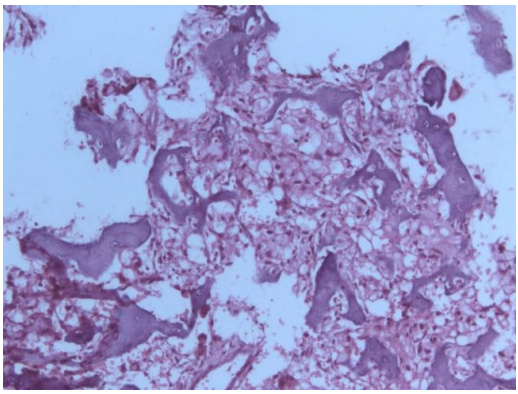

Fig. 5. Microscopic aspects: Spinal metastasis of gastric carcinoma with "signet ring cells" (HE, x10).

Correlations between the histological type of spinal metastasis and the number of erythrocytes

The Kruskal-Wallis test for the comparison of erythrocyte counts between the different histological types of metastases generated the following values: H = 6.21; p = 0.52, which means that there is no statistically significant difference between the values of erythrocyte counts and histological type ($p > 0.05$).

However, it can be observed that, at the moment of their spinal metastases, rectal adenocarcinoma cases presented the lowest erythrocyte counts (2.62×10^6/mL), while neuroendocrine carcinoma of the small intestine showed the highest mean values (4.20×10^6/mL). Intermediate levels were observed in rectal squamous carcinoma (3.3×10^6/mL), colon adenocarcinomas (3.74×10^6/mL), hepatocellular carcinoma (3.80×10^6/mL), and cholangiocarcinoma (4.06×10^6/mL) (fig. 6). These findings suggest potential variations in hematological impact depending on the histological subtype of the primary tumor.

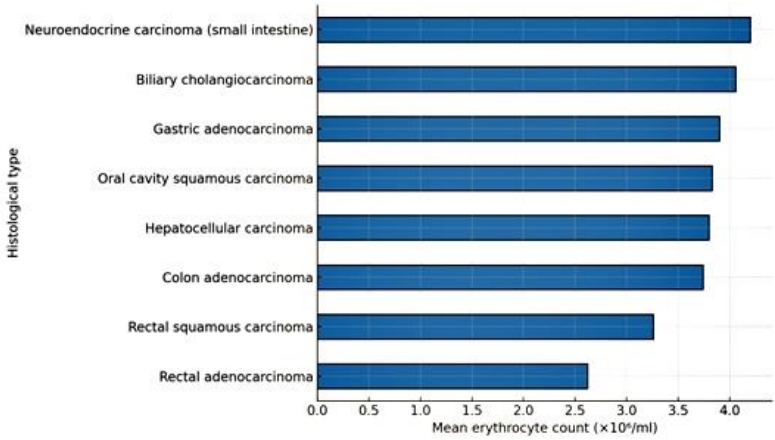

Fig. 6. Bar chart of average erythrocyte count values ($\times10^6$/mL) across different histological types of digestive cancers with spinal metastases in the present series.

Correlations between the histological type of spinal metastasis and hemoglobin value

The Kruskal-Wallis test for comparing hemoglobin values according to the histological type of metastasis generated the following values: H = 6.36; p = 0.50, which demonstrates that there is no statistically significant difference between hemoglobin levels and histological type ($p > 0.05$).

However, it is noted that vertebral metastases from rectal adenocarcinoma cases presented the lowest hemoglobin levels (8.3 g/dL), while cholangiocarcinoma and neuroendocrine carcinoma (small intestine) demonstrated relatively higher averages (>11 g/dL) (fig. 7).

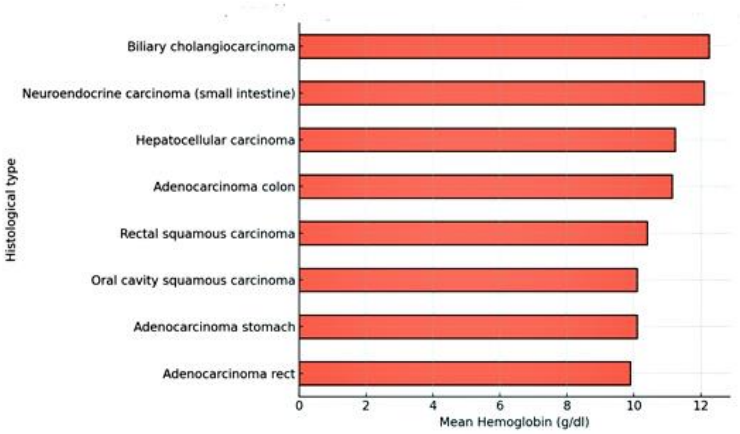

Fig. 7. Mean hemoglobin values (g/dL) by histological type in patients with digestive spinal metastases in the present series.

Correlations between the histological type of spinal metastasis and hematocrit value

The Kruskal-Wallis test for comparing hematocrit values between the different histological types of metastases generated the values: H = 6.21; p = 0.52, which means that there is no significant difference between hematocrit values and histological type ($p > 0.05$).

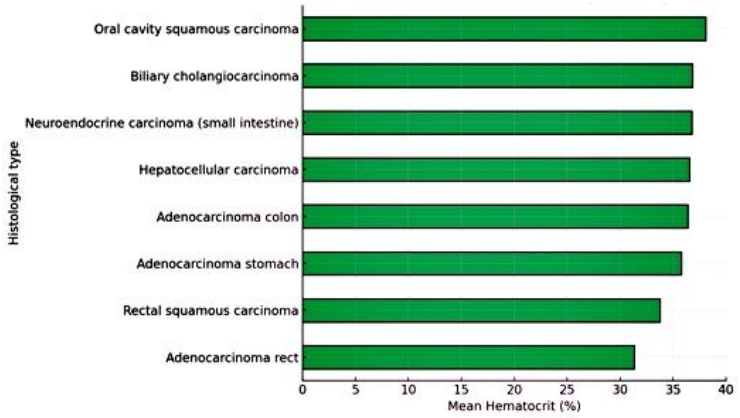

Fig. 8. Average hematocrit values (%) by histological type of digestive spinal metastases in the present series.

However, it is found that spinal metastases of rectal adenocarcinoma cases demonstrated the lowest mean hematocrit (~31%), while spinal metastases of oral cavity squamous carcinoma presented the highest mean values (~38%). Spinal metastases of colon adenocarcinoma, hepatocellular carcinoma, or cholangiocarcinoma showed intermediate levels (36-37%) (fig. 8).

Correlations between the histological type of spinal metastasis and the erythrocyte sedimentation rate value (ESR)

The Kruskal-Wallis test for the comparison of ESR values between different histological types of metastases generated the values: $H = 9.42$; $p = 0.22$, which means that there is no statistically significant difference between ESR values depending on the histological type ($p > 0.05$).

However, it is observed that spinal metastases of oral cavity squamous carcinoma and of rectal adenocarcinoma cases presented with the highest mean ESR values (~60-70 mm/h). Hepatocellular carcinoma (HCC) and colon adenocarcinoma demonstrated intermediate values (~45-55 mm/h), though one HCC patient exhibited an extreme value (130 mm/h). Neuroendocrine carcinoma of the small intestine showed the lowest averages (~25 mm/h). Colorectal adenocarcinomas exhibited median values (~50mm/h), but there were highly variable ESR values, reflecting the heterogeneity of systemic inflammation and disease burden in this subgroup (fig. 9).

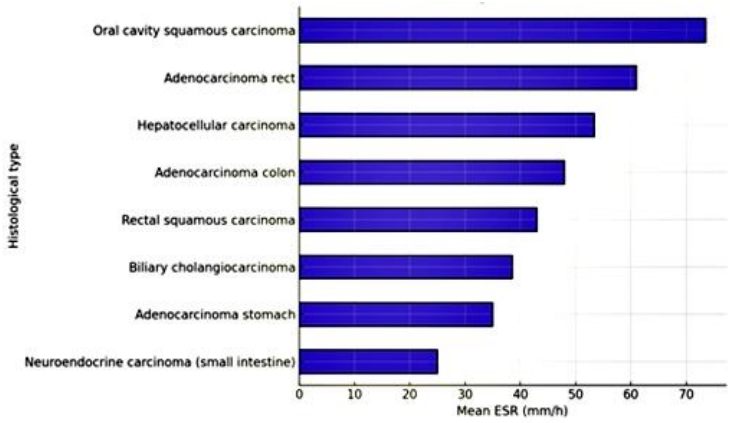

Fig. 9. Average erythrocyte sedimentation rate (ESR) values (mm/hr) by histological type of digestive spinal metastases in the present series

DISCUSSION

This study integrates erythrocyte count (RBC), hemoglobin (Hb), hematocrit (Ht), and erythrocyte sedimentation rate (ESR) from a 27-case cohort of spinal metastases of digestive origin, contextualizing patterns across histological subtypes and their clinical implications for diagnosis, prognostication, and supportive care.

Rectal adenocarcinoma showed the most profound anemia profile (lowest mean RBC, Hb, and Ht), together with higher ESR, suggesting combined iron-deficiency (chronic blood loss) and inflammation. Colon adenocarcinoma displayed intermediate anemia with moderately elevated ESR, indicating heterogeneous systemic inflammation. Our data are in line with literature reporting anemia as the most common extraintestinal symptom, appear-

ing in 30-75% of patients (7).

Hepatocellular carcinoma (HCC) presented intermediate anemia, but ESR values were highly variable (including an outlier at 130 mm/hr), consistent with chronic inflammation/hypersplenism rather than occult bleeding. Some authors have shown that ESR can be a marker of early HCC (8). These data may explain the identification of a high EST value in the present study in the case of spinal metastases of HCC.

Cholangiocarcinoma and neuroendocrine carcinoma of small intestine tended to maintain higher RBC/Hb/Ht and lower ESR, in keeping with relatively indolent bleeding profiles and lower marrow suppression.

Regarding squamous carcinomas, we found out some differences by site: oral cavity squamous carcinoma kept higher Ht/Hb and high ESR, but rectal squamous carcinoma showed lower Hb/Ht with mid-range ESR, probably due to anterior chemo- and radiotherapy. However, in case of rectal squamous carcinoma a higher pre-treatment value of Hb was an independent prognostic factor for overall survival of patients with anal canal cancer (9).

From a pathophysiological point of view, we can take into consideration the following mechanisms:

(1) Rectal primaries frequently drive iron deficiency via chronic bleeding, lowering RBC/Hb/Ht and raising ESR (7). Conversely, HCC-associated anemia is often normocytic and inflammation-driven, compounded by hypersplenism, but it can be significantly associated with mortality in HCC patients, independent of established liver- and tumor-related prognostic factors (10);

(2) Recent chemotherapy and radiotherapy of the primary tumor may transiently suppress erythropoiesis, worsening anemia independently of histology (11).

(3) ESR elevation often correlates with poor prognosis in several types of cancer. There are studies that have demonstrated this correlation in kidney cancer (12), prostate cancer (13), and also in colorectal cancer (14).

(4) Bone marrow involvement in metastatic disease and poor nutrition decrease Hb/Ht, especially in colorectal cancer (15), but NETs and cholangiocarcinoma typically show slower marrow impact and as such hematological indices will not decrease at lower values, but rare cases of cholangiocarcinoma can realize an extensive destruction of bone marrow and present anemia with lower values of Hemoglobin (16).

Our findings have some clinical implications. One of them is the possibility to realize a baseline risk stratification when combining erythrocyte number, Hb, Ht and ESR, because differences of these hematological indices can underline the anatomical site of the primary cancer, and comorbid conditions and may have prognostic and therapeutic relevance.

Some authors demonstrated that Hb is a prognostic factor for spinal metastases. The baseline Hb level is included as a prognostic variable in certain scoring systems for spinal metastasis (17-19).

ESR was also identified as an independent prognostic factor for patients with Spinal Metastasis from Esophageal Cancer (20). Across solid tumors, pre-treatment anemia and elevated ESR associate with poorer survival (21, 22).

In colorectal cancer, both low Hb and high ESR relate to advanced stage; in HCC, inflammatory markers reflect underlying hepatic dysfunction. The histology-linked hematologic patterns suggest that simple

blood tests can refine prognosis alongside imaging and clinical scores as Erythrocyte Sedimentation Rate revealed the inflammation that is associated with development and progression (23), and anemia, revealed by low values of erythrocytes, hemoglobin and hematocrit, often accompany the progression of the metastatic disease and its cause is a defect in iron handling rather than a lack of iron *per se* (24).

CONCLUSIONS

Hematological profile and erythrocytes sedimentation rate (ESR) in spinal metastases of digestive origin show reproducible, histology-specific patterns: rectal primaries cluster with profound iron-deficiency anemia and high ESR; colon adenocarcinoma and hepatocellular carcinoma show intermediate anemia with variable inflammation; cholangiocarcinoma and neuroendocrine tumors of small intestine often preserve hematological parameters with lower ESR. Integrating RBC/Hb/Ht with ESR enhances clinical triage, informs supportive care, and may improve prognostication when embedded in multivariable models.

Histology-specific anemia patterns therefore provide useful insights into prognosis and patient management as it may aid in risk stratification: rectal cancers with low hematocrit at the moment of the spinal metastases' diagnosis may indicate more aggressive systemic disease.

Monitoring hematological analysis dynamics could help guide supportive care, including transfusions and iron supplementation, especially in colorectal cancer patients at risk for profound anemia.

MANAGEMENT OF LEFT ILIAC FOSSA PAIN IN THE EMERGENCY DEPARTMENT (Abstract): Left iliac fossa (LIF) pain is a common reason for emergency department (ED) visits and can be caused by a wide range of conditions, from benign to life-threatening, timely and accurately diagnosis being crucial for appropriate management. This study **aims** to highlight the management of LIF pain and to outline the etiology and imaging findings in a real-world ED setting. **Materials and methods:** We conducted a retrospective study of 144 patients who presented with LIF pain at the ED of Sf. Spiridon County Clinical Emergency Hospital Iași between August 2022 and December 2024. Imaging studies and final diagnoses were analyzed to assess diagnostic pathways and imaging concordance. **Results:** The patients had a mean age of 53.9 years, with a slight female predominance (56.25%), the most frequent diagnoses being acute diverticulitis (25%). Computed tomography (CT) was performed in 105 cases (72.92%) and provided clarification in nearly a third of the patients who had previously undergone ultrasound (US) and didn't have a final diagnosis. Overall, CT findings confirmed the ED's initial diagnostic hypothesis in 75.24% cases. **Conclusions:** This study offers a detailed analysis of CT utility in a real-world emergency setting, confirming that CT plays an important role in the differential diagnosis of LIF pain in the ED, influencing management decisions and improving clinical outcomes. Our data support the implementation of standardized diagnostic algorithms for LIF pain in the ED, incorporating early CT in selected cases in order to ensure a patient-centered approach. **Keywords:** LEFT ILIAC FOSSA PAIN, COMPUTED TOMOGRAPHY, DIVERTICULITIS.

INTRODUCTION

The most common condition for patients' presenting in ED is abdominal pain, the one in the LIF being a frequent symptom and affecting an older population compared to the right iliac fossa pain (1); it is important to find out the etiology (organic or functional, tumoral or infectious) as early as possible because it can be a symptom of an emergency in which case the patient requires an adequate treatment (2).

LIF includes intraabdominal structures (digestive and genito-urinary organs, vessels, lymph nodes) and abdominal wall (3), which can cause visceral, parietal and referred pain together and separately.

Plain abdominal X ray, US and CT, play an important role in the evaluation and management of LIF pain, being able to differentiate rapidly from conditions requiring no treatment to life-threatening emergencies. Plain abdominal X ray is

often the chosen imaging modality due to its availability, low cost, low radiation dose and high amount of information (evaluates bones, foreign bodies, air filed structures and offers limited detail on the soft tissues). US is non-invasive and fast but is operator dependent and doesn't pass through bone or gas (4). CT creates cross-sectional images, is standardized, uses a higher amount of ionizing radiation but provides a higher amount of diagnostic information than plain abdominal X ray (5,6); it is also fast (image acquisition takes 5 to 10 minutes from patient positioning to the end of the procedure and another 10 to 30 minutes for the written report), but sometimes patients can have adverse reactions to intravenous contrast medium. Radiologists and emergency doctors must adequately choose between plain abdominal X ray, abdominal and pelvic US and abdominal and pelvic contrast enhanced CT (CECT), depending on the suspected diagnosis and patient's specificity, in order to quickly assess injuries, identify life-threatening pathologies, and guide immediate patient management (7).

The most frequent causes of LIF pain are gastrointestinal diseases: constipation, irritable bowel syndrome (IBS), acute diverticulitis, colitis, bowel obstruction and tumors, sigmoid volvulus, hernias, epiploic appendicitis, digestive foreign bodies.

Colonic diverticulosis is the most frequent bowel condition in Europe (appearing in over 70% of the population by their eighties), most patients remaining asymptomatic (8). Diverticulitis can cause only localized inflammation but sometimes (12% of cases) is complicated with abscess, fistula, perforation, bowel obstruction or hemorrhage. Endoscopic procedures are generally contraindicated in cases of suspected acute diverticulitis, due to a high risk of perforation, so imaging methods play an important role in diagnosis (9).

Acute colitis reunites a wide range of bowel conditions, so discerning the specific cause of the disease is challenging, CECT frequently provides an initial evaluation, offering suggestive signs and aiding to clarify the underlying etiology (10).

CT is a valuable diagnostic tool for two self-limiting inflammations causing abdominal pain: acute epiploic appendicitis, mainly located frequently in LIF and omental infarction frequently on the right side of the abdomen, rarely causing pain in the LIF (11).

Colorectal cancer is an increasingly pressing global health concern, left side locations being more likely to be complicated with bowel obstruction, but also with progressive left iliac fossa pain, rectal bleeding and unexplained weight loss. Data indicates that men are more frequently affected (53% *vs.* 47%) and earlier in life (68 years *vs.* 72 years in women). The incidence of this condition in younger adults is also climbing. Many cases are sporadic, influenced by factors such as advanced age, racial background, diet, and a history of inflammatory bowel disease (12).

MATERIALS AND METHODS

We conducted a retrospective study on a cohort of 144 patients who presented to the Emergency Department (ED) of Sf. Spiridon County Clinical Emergency Hospital Iași between August 2022 and December 2024 with LIF pain, either as an isolated symptom or associated with other types of abdominal or lumbar pain.

The inclusion criteria were straightforward: the presence of LIF pain clearly documented in the ED observation sheet,

either in the patient's medical history or in the clinical examination. Cases were excluded if abdominal pain was mentioned without a clearly specified location or without identifying the point of maximum intensity.

A systematic review of ED observation sheets was carried out both manually and electronically, using keywords such as "LIF pain". Although not all parameters were available for every patient, the dataset included key clinical and administrative variables whenever possible. These included patient demographics such as age and sex; timing of ED events, including the moment of ED sheet initiation, time of first medical evaluation; signs and symptoms recorded during the visit, relevant medical history (previous surgeries, chronic conditions), imaging methods.

The statistical analysis aims to characterize the patient cohort, explore relevant clinical correlations and compare with findings reported in the literature.

RESULTS

The patients had an age range between 18 and 93 years old, with a mean age of 53,9 years. The most common age group was 61-70 years old, accounting for 33 cases, while the least represented were patients over 90 years old, with only one case. Gender distribution was nearly equal, with 47.36% males and 52.64% females, a ratio consistent with that of the general Romanian population. Minor variations may reflect the limited sample size, but they also raise relevant questions regarding differences in symptom perception and care-seeking behavior. Women are often more proactive in addressing health concerns, which might explain their slight predominance in this cohort.

Time spent in the ED plays a critical role in patient management and ensures prompt initiation of treatment. In this study, triage time (interval between the opening of the ED observation sheet and the first medical consultation) ranged from 0 to 250 minutes, with a mean value of 30 minutes. The cumulative time spent in the ED calculated from the time of completing the ED observation sheet until the time of closing the sheet due to admission, transfer to another hospital, discharge with recommendations, or leaving the ED without medical advice, ranged from one to 18 hours. During this time, patients underwent clinical evaluation (including consultations in gastroenterology and surgery departments), blood and urine tests, imaging investigations.

The longest recorded delay, 250 minutes (4 hours and 10 minutes), was noted in the case of a patient with uncomplicated acute diverticulitis. Such prolonged waiting times, although isolated, can increase patient anxiety and discomfort, and may lead to delays in diagnostic procedures and the start of appropriate treatment. At the other end were 9 patients (6.25%) triaged as Red Code (NOW: 0-1 minute), with the following diagnoses: LIF stab wound, ruptured ectopic pregnancy, septic shock (abscess and possible tumor recurrence), lipothymia (acute diverticulitis and pulmonary thromboembolism), syncope (small bowel intussusception on imaging and heart failure diagnosed by the cardiologist), 2 patients with generalized stercoral peritonitis due to sigmoid diverticulum perforation post-chemotherapy, 2 thoraco-abdominal contusions (incidental finding of colonic malignant tumors on CT scan). These findings prove that cardiovascular diseases and tumors associated with acute abdominal conditions must be careful-

ly evaluated by a multidisciplinary team (13, 14).

The cumulative distribution curve revealed that more than half of the patients (51%) were triaged within the first 15 minutes, and over 80% within one hour. In contrast, only 18% of patients completed their ED stay within 4 hours, while nearly two-thirds (65%) remained in the department for 4–8 hours. This discrepancy highlights the efficiency of the triage process but also indicates prolonged diagnostic and management phases within the ED workflow (fig. 1).

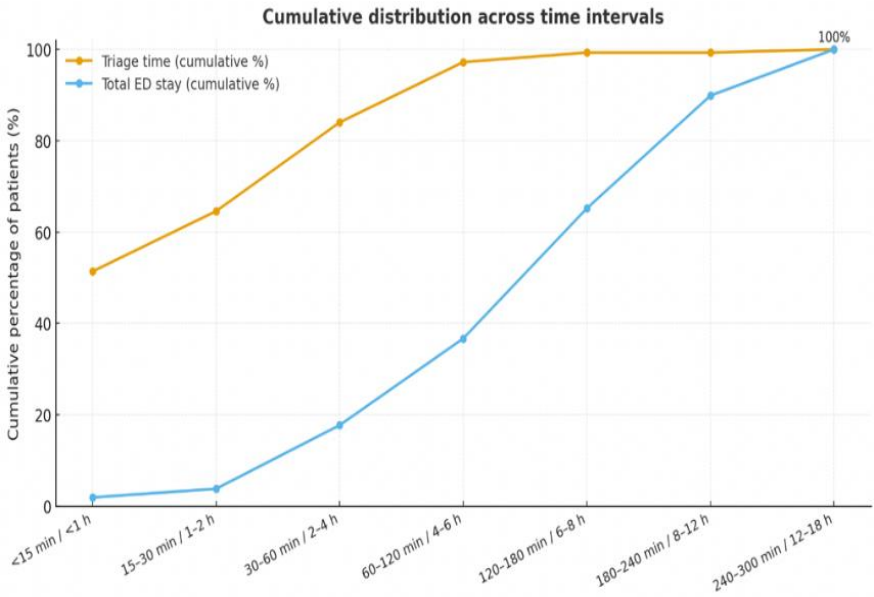

Fig. 1. Cumulative distribution across time intervals (triage time *vs*. total ED stay)

Patients presenting with LIF pain underwent the following imaging investigations: 128 patients (88.89%) underwent abdominal and pelvic US. Which was the most frequent imaging modality used, followed by abdominal and pelvic CECT (105 patients -72.92%), especially valuable when US was inconclusive. Plain abdominal X-ray was used in only 52 cases (36.11%), with limited diagnostic value compared to US and CT, diagnosing bowel obstruction or digestive tract perforation: 27 exhibited hydro-aeric levels (one of the patients also presented a metallic foreign body located in LIF), 23 showed no significant pathological findings, while one revealed a left ureteral calculus.

There was no evidence of pneumoperitoneum on plain abdominal X-ray, however, subsequent abdominal and pelvic CECT identified intraperitoneal air in two cases. This discrepancy underscores a higher CT sensitivity in detecting small volumes of extraluminal gas. The findings align with existing literature that highlights CT's enhanced diagnostic accuracy for pneumoperitoneum, particularly in cases where radiographic results are inconclusive. 7 (4.86%) patients underwent both US and plain abdominal X – ray, 47 (32.64%)

were examined by US and CECT, while in 45 (31.25%) cases, US, plain abdominal radiography and CECT were used together.

Among the 92 patients who underwent both abdominal US and abdominal and pelvic CECT, concordant findings were observed in 65 (29.35%) cases, and in 27 (70.65%) cases, US did not reveal any significant findings related to the patients' presenting symptoms, whereas CT imaging provided diagnostic insights. This discrepancy underscores the complementary roles of US and CT in the evaluation of LIF pain. While US is a non-invasive, radiation-free, and readily accessible imaging technique, its diagnostic accuracy can be limited by factors such as operator dependency and patient body habitus. Conversely, CT imaging offers higher sensitivity and specificity in detecting abdominal pathologies, particularly in complex or inconclusive cases.

CECT had a concordance rate of 75.24% (79 cases) with the initial ED diagnostic hypothesis; in 26 cases (24.76%) CT did not confirm the preliminary diagnosis. This finding demonstrates the significant role of CT in validating clinical assessments, while also highlighting its importance in identifying alternative diagnoses when initial clinical evaluation is inconclusive. The findings affirm the necessity of integrating imaging results with clinical judgment and laboratory testing, to enhance diagnostic accuracy and optimize patient management strategies.

The distribution of final diagnoses among patients presenting with LIF pain was diverse, reflecting a wide range of underlying pathologies (tab. I). The Gini coefficient (fig. 2) was applied to quantify the inequality in the distribution of final emergency department (ED) diagnoses. In this context, a Gini index of 0.45 indicates a moderate concentration of cases within a limited number of etiologic entities. This finding demonstrates that abdominal pain in the ED is not randomly distributed across a wide spectrum of conditions, but rather dominated by a few diagnostic categories-chiefly genitourinary disease (28.47%) and diverticular disease (27.08%)-which together accounted for more than half of all cases. Such a distribution pattern underscores the importance of focusing diagnostic resources and imaging protocols on the most prevalent and clinically significant causes, rather than applying uniform, broad-spectrum diagnostic pathways to all patients.

TABLE I.

ED final diagnoses of patients with LIF pain

ED final diagnosis	No. / %	Observations
Genito-urinary disease	41 (28.47%)	26 (18.05%) left renal colic
		10 (6.94%) left adnexal masses
		2 (1.38%) bladder tumors
		1 (0.69%) left ureter tumors
		1 (0.69%) ruptured ectopic pregnancy
		1 (0.69%) left-side testicular cancer
Diverticular disease (DS)	39 (27.08%)	36 (25%) diverticulitis
		3 (2.08%) uncomplicated DS
Intestinal tumors	15(10.41%)	14 (9.72%) colon cancer
		1 (0.69%) gastro-intestinal stromal tumor

ED final diagnosis	No. / %	Observations
Intestinal obstruction	13 (9.02%)	6 (4.16%) adhesions
		2 (1.38%) intestinal intussusception
		1 (0.69%) small bowel diverticulum
		1 (0.69%) sigmoid volvulus
		1 (0.69%) stenosis (Crohn's disease)
		1 (0.69%) fecal impaction
		1 (0.69%) stoma complication
No significant pathological findings	10 (6.94%)	-
Epiploic appendicitis	7 (4.86%)	6 (4.16%) acute
		1 (0.69%) chronic
IBS	6 (4.16%)	-
Abdominal wall pathology	5 (3.47%)	2 (1.38%) abscesses
		3 (2.08%) hematomas
Abscesses	4 (2.77%)	2 (1.38%) intra-abdominal
		2 (1.38%) iliopsoas region.
Other findings	4 (2.77%)	1 (0.69%) stab wound
		1 (0.69%) acute appendicitis
		1 (0.69%) left inguinal hernia
		1 (0.69%) ruptured aortic aneurysm

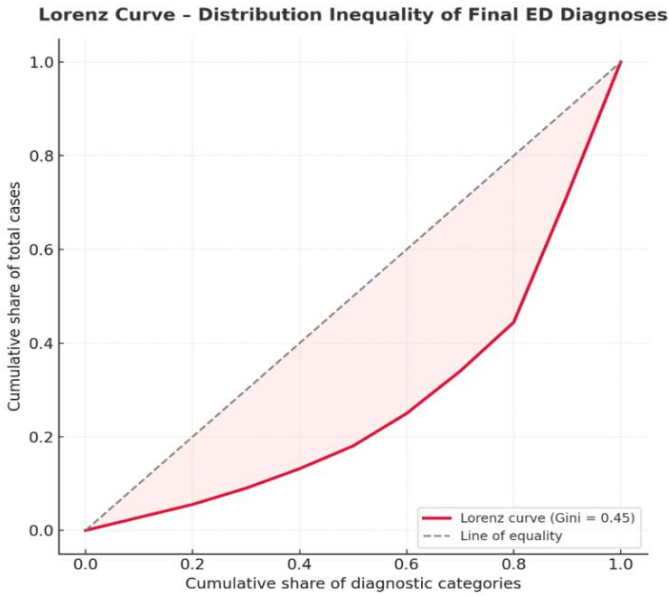

Fig. 2. Lorenz curve illustrating the unequal distribution of final ED diagnoses.

Patients included in the studied group had coexisting chronic health conditions, among them 52 patients (36.11%) had heart conditions, often with two or more diseases present simultaneously, 10 (6.94%) reported respiratory phenomena (dyspnea, cough) or declared non-specific symptoms: headache (37 patients, 25.69%), lipothymia (2 patients, 1.38%). Within the studied cohort, 50 patients (34.72%) had a history of prior surgical interventions, among them two patients (1.38%) had mastectomy and 48 (33.33%) abdominal and pelvic surgery, including 14 (9.72%) with surgery related to various malignant tumors (digestive tract, ovaries, breast, thyroid, and testes). The presence of previous abdominal and pelvic surgery is clinically significant, as it may predispose patients to postoperative adhesions, leading to bowel obstruction or chronic pelvic pain, and can influence both the differential diagnosis and the choice of imaging modalities. Furthermore, a history of cancer-related surgery requires careful consideration, as these patients may have an increased risk of disease recurrence or metastasis, which could manifest as abdominal pain. Therefore, their prior oncological history should be integrated into the diagnostic process to ensure comprehensive evaluation and appropriate management (fig. 3).

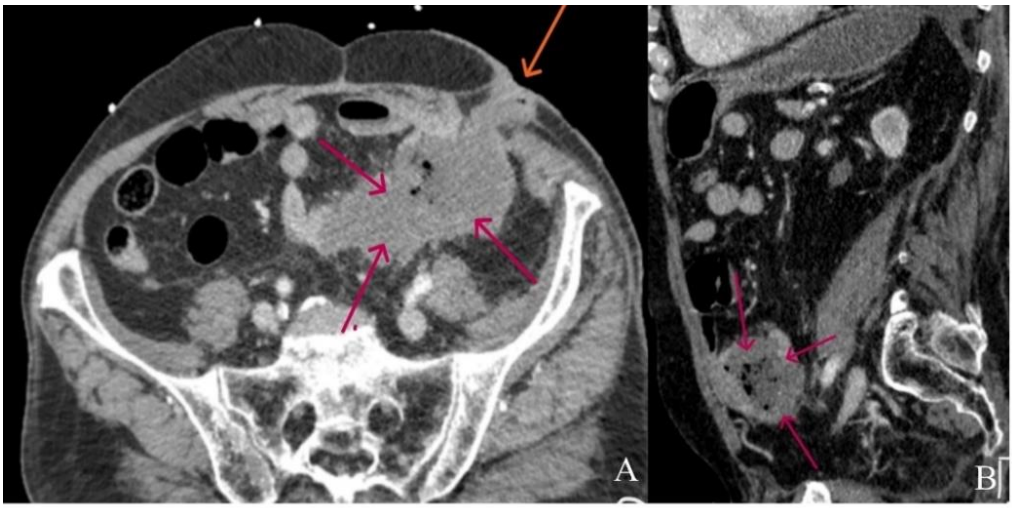

Fig. 3. CECT - colostomy for colonic cancer (orange arrow), collection with gas bubbles (red arrow): axial section (A), coronal multiplanar reconstruction (B)

The Gini coefficient (0.46) indicates that a small number of diagnostic entities account for a disproportionately large share of emergency abdominal presentations.

DISCUSSION

The results of this study have limitations. Being a retrospective, single-centered study, the results may be influenced by the specific practices of this unit and have limited generalizability. Additionally, this analysis is based on data available in patients' charts, which may be incomplete or have variations in the detail

of the information.

Due to its low cost, accessibility, rapid results and lack of ionizing radiation, abdominal US is the first imagistic method of choice for investigating left iliac fossa pain, especially in young female patients (15), but CT has an overall view of the entire patients' pathology.

The main purpose is to analyze the role and added value of CECT in the differential diagnosis of LIF pain. Our study demonstrated that CT is an effective imaging modality and identified a wide range of causes of LIF pain, highlighting the limitations of clinical examination and laboratory tests in establishing a precise etiological diagnosis in the ED and underscores the necessity of using advanced imaging methods (16).

In case of patients with malignancies or complex inflammatory conditions, early identification of complications such as abscesses or fistulas allowed more appropriate surgical planning and, in some cases, avoided unnecessary exploratory laparotomies (2).

The patients' history of prior surgical interventions, especially for breast and abdominal and pelvic malignant tumours, can predispose patients to postoperative adhesions, have an increased risk of tumor recurrence or metastasis, which can manifest with abdominal pain; therefore, the oncological history should be considered in imaging evaluation to ensure an appropriate management (17).

Patients who have coexisting heart conditions, lipothymia, respiratory phenomena have to be carefully monitored by clinicians in order to avoid complications after intravenous administration of iodinated contrast media for CECT examination (13,18). Radiologists have to notice significant subtle diagnoses that need urgent intervention, reducing errors by reviewing all available clinical and paraclinical notes, working in a team, analyzing all medical imaging, especially all CT phases (noncontrast and postcontrast: arterial, portal and late), by having a systematic approach and by using multiple windows and multiplanar reconstruction (19).

Diagnostic discrepancies observed in 24.76% of cases between the ED clinical assessments and CT findings emphasize the inherent limitations of initial clinical judgment, particularly in a high-pressure emergency environment.

The calculated Gini coefficient was 0.45, reflecting a moderate inequality in diagnostic distribution. Most cases were concentrated in two major categories-genitourinary disease (28.47%) and diverticular disease (27.08%).

CONCLUSIONS

This study offers a detailed analysis of CT utility in a real-world emergency setting, confirming that CT plays an important role in the differential diagnosis of LIF pain in the ED, influencing management decisions and improving clinical outcomes. Our data support the implementation of standardized diagnostic algorithms for LIF pain in the ED, incorporating early CT in selected cases in order to ensure a patient-centered approach.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

SOLITARY AND MULTIPLE ENCHONDROMAS (OLLIER DISEASE): RARE SKELETAL DISORDERS CAUSING SEVERE BONE DESTRUCTION AND PSYCHO-EMOTIONAL DISTRESS (Abstract): Solitary enchondromas represent benign cartilaginous neoplasms originating from residual chondrocytes of the physeal plate. Ollier disease (multiple enchondromatosis) is a rare, non-hereditary skeletal disorder characterized by multiple intramedullary cartilaginous tumors (enchondromas) carry a risk of malignant transformation into chondrosarcoma or atypical cartilaginous tumor (ACT). Both diseases are rare, initially asymptomatic and curative treatment is non-existent. **Materials and methods**: The study included a cohort of 14 patients diagnosed with solitary or multiple asymptomatic enchondromas, classified according to the Takigawa classification. in all cases the diagnosis was established by imaging examination. All patients underwent surgical treatment. The surgical techniques employed consisted of tumor curettage followed by reconstruction of the resulting bone defect using either autologous bone graft or solid bone substitute. In one case, where the enchondromas were multiple and large, with massive digital bone destruction, a necessary amputation was performed. **Results**: Imaging examinations revealed extensive lytic lesions affecting the metacarpals and phalanges in all cases. In the patient with Ollier disease, lesions were also identified in the radius, humerus, scapula, and vomer bone-an exceptional localization. Histopathological analysis confirmed a central atypical cartilaginous tumor (ACT) arising secondarily from an enchondroma in the case of multiple enchondromatosis. The patient with Ollier disease was also diagnosed with psychiatric comorbidities, including anxiety and depression, related to chronic hospitalization and physical deformity. Functional and aesthetic outcomes were evaluated in all cases using the DASH, ROM, and VAS scores. **Conclusions**: The presence of enchondromas is rare, and multiple enchondromatosis-particularly when associated with cranial involvement-represents an extremely uncommon entity. The absence of symptoms often leads to incidental diagnosis. In Ollier disease, onset occurs in early childhood, and the resulting deformities can cause significant psychological and emotional trauma, in addition to the orthopedic and functional burden associated with the disease. **Keywords:** SOLITARY ENCHONDROMA; OLLIER DISEASE; CHONDROSARCOMA; VOMER BONE ENCHONDROMA; SURGERY.

INTRODUCTION

Solitary enchondromas represent benign cartilaginous neoplasms originating from residual chondrocytes of the physeal plate. More than half of the reported cases are localized within the bones of the hand (1).

The true incidence of this pathology is likely underestimated, as enchondromas frequently remain clinically silent. Diagnosis is most often established incidentally during routine radiographic evaluation or in response to clinical manifestations such as localized pain, swelling, or a pathological fracture. Radiographic examination typically demonstrates a well-circumscribed lytic lesion that generally preserves cortical integrity and does not involve adjacent soft tissues, with variable degrees of intralesional calcification (2, 3).

The management of benign osseous tumors of the hand, including enchondromas, typically involves intralesional curettage, with or without subsequent filling of the residual cavity using autologous bone graft or bone substitute material (4). Although autologous bone grafting remains the gold standard for reconstructing bone defects, the use of bone substitutes has become increasingly prevalent in order to minimize donor-site morbidity and associated complications. In cases requiring cancellous bone grafting for hand defects, the distal radius and the olecranon of the ulna are the most commonly utilized donor sites. These locations generally provide sufficient cancellous bone for reconstruction of defects in the carpal bones, metacarpals, and phalanges, and are preferred due to their accessibility within the same operative field and compatibility with the same regional anesthesia (5, 6).

Multiple enchondromatosis also known as Ollier disease, is a rare, non-hereditary skeletal disorder that occurs sporadically and was first described in 1889 by Louis Léopold Ollier (1, 2). It is typically diagnosed in early childhood, manifesting through painful bone deformities, limb asymmetry, and growth disturbances. The estimated incidence of the disease is approximately one case per 100,000 individuals, making it an exceptionally uncommon condition (3). In Ollier disease, multiple enchondromas are irregularly distributed and may appear either unilaterally or symmetrically, varying in both number and stage of development (4, 5). The diagnosis is primarily based on clinical evaluation and imaging studies, with histopathological assessment being essential to identify malignant transformation-most frequently into chondrosarcoma or, less commonly, osteosarcoma (1). The reported risk of malignant transformation ranges between 5% and 50%. Since 2013, the World Health Organization (WHO) has reclassified grade I chondrosarcoma as an atypical cartilaginous tumor (ACT), recognizing it as a locally aggressive neoplasm with limited metastatic potential and classifying it as an intermediate-grade rather than a fully malignant tumor (2, 3).

These lesions can lead to progressive bone destruction, skeletal deformities, and functional disability, often beginning in childhood and persisting into adulthood (6). The visible deformities, coupled with chronic pain and restricted movement, frequently result in psychological distress, including anxiety, low self-esteem, and depressive symptoms, which significantly affect the patient's quality of life (1, 7).

Despite being a rare and debilitating condition with a significant risk of malignant transformation, there is currently no specific curative treatment for Ollier disease (2). Patients presenting with small, asymptomatic enchondromas that do not compromise limb function are typically managed through careful clinical and radiological observation. Surgical treatment is indicated only in cases complicated by limb shortening, severe deformities, pathological fractures, or suspected malignancy (8). Depending on the extent and severity of

bone destruction, surgical approaches may include tumor excision followed by bone grafting, either using autologous bone or synthetic bone substitutes (9). The bone substitute can be solid or injectable, and may also be employed in the absence of an autologous graft (9). When cortical thinning remains significant after tumor ablation, osteosynthesis materials such as Kirschner wires, plates and screws, or external fixators can be used to reinforce bone stability and prevent postoperative fracture. In extensive lesions with severe cortical destruction where reconstruction is not feasible, amputation of the affected segment may be the only viable treatment option (10).

Advanced imaging modalities, including MRI and CT, are critical in determining the extent of the lesions, assessing cortical involvement, and detecting early malignant transformation. Bone scintigraphy may also be used to evaluate metabolic activity and identify lesions with aggressive potential (11, 12). Imaging studies are further valuable in identifying associated systemic abnormalities, as Ollier disease has been linked to conditions such as skull base gliomas, pancreatic neoplasms, and hematologic disorders, supporting the concept of a broader systemic predisposition related to somatic mosaicism (13).

We report a retrospective study including 13 patients diagnosed with unilateral solitary enchondroma of the hand and one patient diagnosed with multiple enchondromatosis (Ollier disease), with lesions also involving the vomer bone and significant psychiatric impairment.

MATERIALS AND METHODS

A total of 14 patients, aged between 23 and 54 years, were included in this study. All were admitted to the Plastic Surgery Clinic of Sf. Spiridon County Clinical Emergency Hospital Iasi between 2016 and 2023.

The study was approved by the institutional ethics committee, and informed consent was obtained from all participants. All patients presented with slow-growing, painless deformities of the metacarpal or phalangeal bones. None of the cases reported pain or sensory disturbances. In five cases, patients presented to the emergency department with pathological fractures resulting from minor trauma, such as direct blows or falls from standing height. One patient was known to have Ollier disease (multiple enchondromatosis), diagnosed at the age of three, associated with psychiatric pathology secondary to physical deformities. The reason for medical presentation in this case was the excessive tumor volume involving both hands, particularly the second finger of the right hand. Radiological imaging was performed in all cases, while computed tomography (CT) was additionally conducted in the patient with Ollier disease. Surgical treatment was indicated in all patients. Surgical interventions were carried out under either WALANT (Wide Awake Local Anesthesia No Tourniquet) or loco-regional infraclavicular block anesthesia. All excised specimens were submitted for histopathological examination. Postoperative outcomes were assessed over a two-year follow-up period, using the DASH, ROM, and VAS scoring systems.

RESULTS

The study included 14 patients aged between 23 and 54 years (mean age 38.5 years), of whom 12 were male (85.7%) and 2 were female (14.3%). Thirteen patients presented with unilateral solitary enchondroma of the hand, while one patient was

diagnosed with multiple enchondromatosis (Ollier disease), representing 7.1% of the cohort (tab. I).

TABLE I.

Baseline Characteristics

Variable	Value
Total patients	14
Age range (years)	23-54
Mean age (approx.)	38.5
Sex: Male	12 (85.7%)
Sex: Female	2 (14.3%)
Lesion type: Solitary	13 (92.9%)
Lesion type: Multiple (Ollier)	1 (7.1%)
Laterality	Unilateral in 13, bilateral in 1 (Ollier)
Anatomic sites (hand)	11 phalanges, 1 metacarpal, 1 multifocal (Ollier)

Among the solitary cases, enchondromas were localized in 11 patients at the level of the phalanges—specifically, two cases involved first phalanx of middle finger of the left hand, five cases first phalanx of the fifth finger of the right hand, three cases first phalanx of the fifth finger of the left hand, and one case third phalanx of the fifth finger of the left hand. One lesion was situated in the second metacarpal.

The patient with Ollier disease presented with multiple lesions affecting both hands (phalanges and metacarpals), bilateral radius, humerus, scapula, and, exceptionally, the vomer bone (fig. 1).

Radiological exam confirmed the presence of well-circumscribed lytic lesions in all cases (fig. 2).

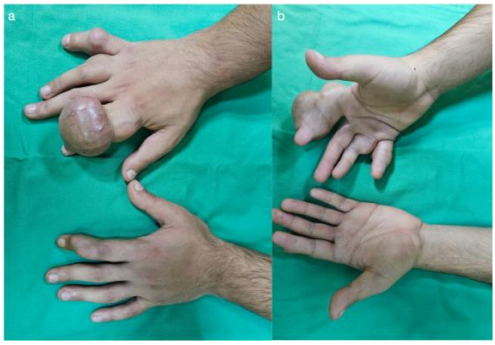

Fig. 1. Clinical aspect of the both hands. a. dorsal aspect, b. palmar aspect

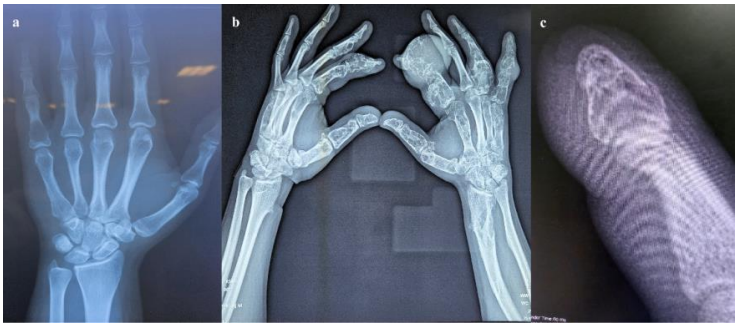

Fig. 2. Radiological aspect of a solitary enchondroma a. first phalanx of the fifth finger, b. distal phalanx of the medius finger, c. multiple enchondromatos

The lesions typically demonstrated cortical thinning without rupture, endosteal scalloping, and occasional intralesional calcifications. No periosteal reaction or soft-tissue extension was observed. These radiographic features were consistent with the benign appearance of enchondromas and supported the indication for conservative surgical curettage.

For the patient with Ollier disease, combined clinical and imaging assessments established the diagnosis of multiple enchondromatosis (Ollier disease), which was subsequently confirmed by genetic testing. Multiple surgical interventions had been performed throughout childhood and adolescence. By the age of 18, the patient's medical history included Ollier disease, a pathological spiral fracture of the distal third of the left femur with displacement (surgically treated in 2010), left genu valgum (surgically corrected in 2024), limb length discrepancy with a 9 cm shortening of the right lower leg, bilateral knee stiffness, and generalized growth delay. Given the cumulative burden of prolonged hospitalizations, repeated surgeries, skeletal deformities and asymmetries, combined with a disrupted family and social environment, the patient was diagnosed with an organic personality disorder, chronic sleep disturbances, generalized anxiety disorder, and severe depressive episodes with anxiety paroxysms. He has been under psychiatric care since the age of 16. Between the ages of 18 and 26, the patient did not seek medical follow-up regarding the progression of his condition. At the time of current admission, clinical examination revealed marked deformities involving the metacarpals and phalanges of both hands, which were asymmetrical and varied in size.

Preserved and symmetrical cutaneous sensitivity was noted. In the right hand, both active and passive opposition movements were impaired due to limited flexion of the 2nd, 4th, and 5th digits, resulting in an inability to perform a cylindrical grasp. Additionally, all previously documented skeletal deformities were clinically confirmed.

The CT scan reveals, in case of multiple enchondromatosis, multiple expansile lytic bone lesions consistent with enchondromas, some exhibiting heterogeneous structure with internal calcifications. Several lesions demonstrate cortical disruption with soft tissue extension and significant bone deformities, particularly in the hand skeleton. No periosteal reactions are noted. The lesions are more numerous in the right upper limb. In the right radius, at the distal third, multiple lytic expansile lesions with cortical breach and mild soft tissue extension are observed, with a maximum size of 12×25 mm.

In the right humerus, a central, expansile lytic lesion with calcifications is seen in the proximal metaphysis, causing cortical thinning without periosteal reaction, measuring 20×34×36 mm. A similar centro-medullary lesion with calcifications (9×13 mm) is noted in the mid-diaphysis, with mild asymmetric cortical thinning. The right scapula (partially included in the scan) shows multiple lytic lesions, particularly in the coracoid process, with the largest measuring 18 mm. The left humerus has a large, central osteolytic lesion extending from the proximal metaphysis into the diaphysis, occupying nearly half its length, with cortical thinning and focal erosions, particularly in the metaphyseal region, with a cranio-caudal diameter of 110 mm. The left scapula (partially included) contains similar lytic lesions, mainly in the coracoid

process, with the largest measuring 14 mm. Additional lesions are seen in the pisiform and triquetral bones, with significant cortical lysis in the pisiform. In the left hand, numerous lytic lesions affect the phalanges, albeit smaller than those on the right. Some exhibit cortical thinning, focal disruptions, and extra-osseous extension, with the largest at the first phalanx of the thumb measuring 16×13×17 mm. Small osteolytic lesions are also present in the carpal bones, some with cortical thinning. In the left radius, a central osteolytic lesion in the proximal metaphysis shows mild expansion and cortical thinning, measuring 13 mm (fig. 3).

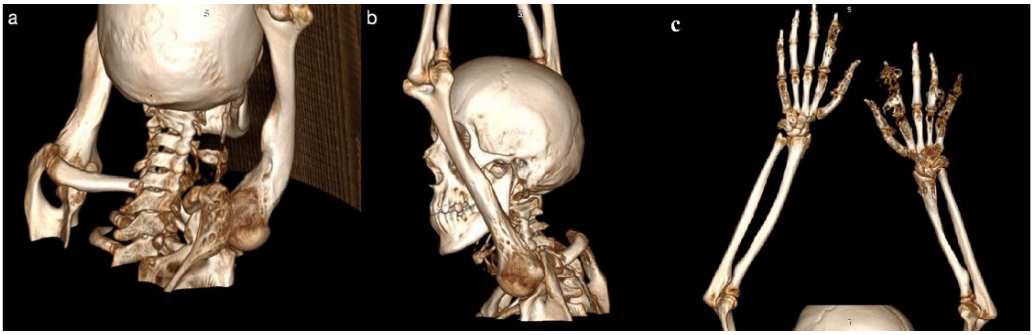

Fig. 3. CT imaging. a, b. Enchondromas located in bilateral humerus and the left scapula.

In the right hand, extensive lytic lesions affect the metacarpal bones and phalanges, sparing only the third digit. Most lesions show cortical thinning or focal disruptions, with a particularly large, expansile lesion in the second digit (notably involving the proximal and middle phalanges), measuring 48×50×39 mm, with gross cortical destruction and extra-osseous extension, c. Enchondromas involving the metacarpals and phalanges of both hands, as well as the distal end of the left radius

Additional findings include an expansile lytic lesion with cortical irregularities and interruptions in the vomer bone, associated with nasal septum deviation to the left (fig. 4).

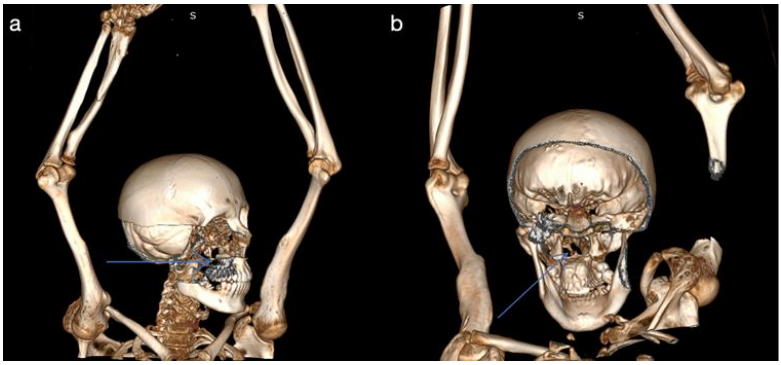

Fig. 4. CT appearance of an enchondroma located in the vomer bone-destruction of the vomer bone: a. lateral view, b. posterior view.

A C2-C3 vertebral block is present, and, despite significant artifacts, cystic areas are noted in the posterior fossa (19×23 mm), suggestive of arachnoid cysts or a mega-cisterna magna. The right thyroid lobe is heterogeneous, containing a hypodense nodule of 9×8 mm, and a similar posterior left thyroid nodule of 9×8 mm is also noted.

Based on the patient's history, clinical findings, and imaging results, surgical intervention was deemed necessary at the level of the second digit of the right hand, which was causing significant functional impairment. This limitation represented the main reason the patient sought medical attention (tab. II).

TABLE II.
Operative Details

Parameter	Findings
Anesthesia	8 loco-regional (infraclavicular block), 6 WALANT (1: 100,000 dilution)
Type of surgical procedure	Intralesional curettage ± cavity filling in 13 cases; amputation in 1 case (Ollier)
Osteosynthesis material	Used in 13/14 cases (92.9%)
Bone grafting	Autologous bone graft in 3 cases (21.4%)
Bone substitute	Solid bone substitute in 10 cases (71.4%)
Fixation stability	Achieved in all reconstructed cases
Fixation stability	Achieved in all reconstructed cases
Amputation (necessity)	1 case - Ollier disease, large tumor (6.5×5×5.8 cm)

Loco-regional anesthesia (infraclavicular block) was used in eight patients (57.1%), while the WALANT technique (1: 100,000 dilution) was used in six (42.9%). Surgical management consisted of intralesional curettage with or without cavity filling in 13 cases (92.9%), and amputation was required in one case due to massive bone destruction secondary to multiple enchondromatosis.

For reconstruction, autologous bone grafts were used in three patients (21.4%), whereas solid bone substitutes were applied in ten (71.4%). Osteosynthesis material was employed in 13 of 14 cases (92.9%) to ensure structural stability (figs. 5, 6).

In the patient with multiple enchondromatosis, amputation was required due to the considerable tumor dimensions (6.5×5×5.8 cm) and the presence of extensive osseous destruction.

All curetted specimens were submitted for histopathological analysis. In patients with solitary enchondromas, no signs of malignant transformation were identified (0/13) (tab. III).

In contrast, histopathological evaluation of the giant tumor in the patient with multiple enchondromatosis revealed a mesenchymal tumor proliferation involving the phalangeal structures of the second digit of the right hand, characterized by a multilobular growth pattern, consistent with a secondary atypical cartilaginous tumor (ACT). The lesion was composed of an abundant cartilaginous matrix, forming multiple lobules of irregular size and shape, separated by fibrous septa with congested vasculature. Areas of both low and high cellularity were observed. The chondrocytes showed minimal to moderate cytonuclear pleomorphism, with well-preserved eosinophilic cytoplasm and irregular, unequal, hyperchromatic nuclei. The nuclei displayed variable morphology, ranging from lymphocyte-like to stellate and fusiform shapes.

Occasional typical mitotic figures were identified. Focally, regions with marked pleo-morphism and increased density of atypical tumor cells were also noted (fig. 9).

TABLE III.
Imaging and Histopathological Findings

Variable	Findings
Imaging findings	Lytic lesions in all 14 cases (100%)
Solitary lesions	No malignant transformation identified (13/13)
Multiple enchondromatosis (Ollier)	Mesenchymal tumor proliferation with multilobular growth pattern, consistent with secondary ACT

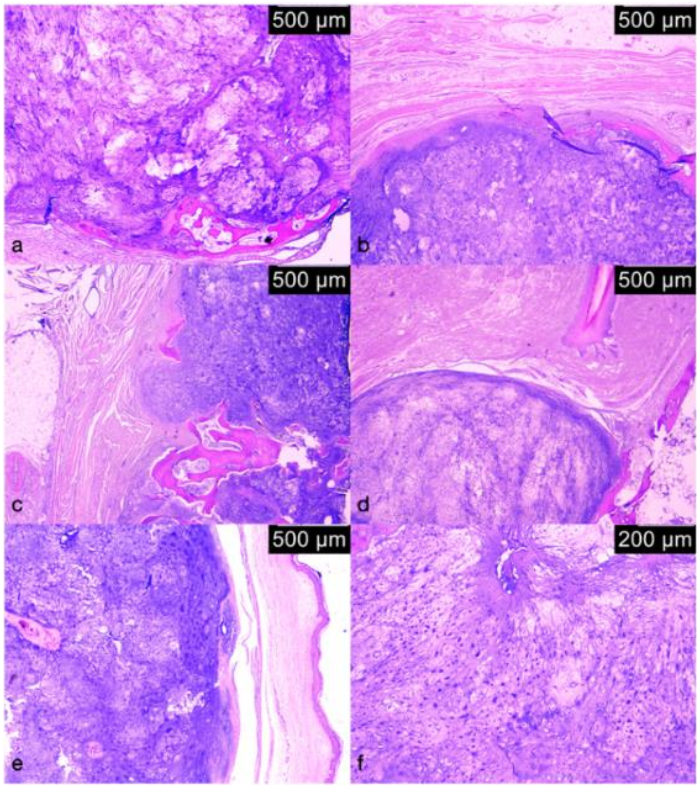

Fig. 8. a. ACT-cortical bone destruction with invasion into adjacent connective tissue (×2.5); b. ACT- cortical bone destruction with invasion into an adjacent ligament (×2.5); c. ACT- cortical destruction with soft tissue invasion (×2.5); d. ACT- invasive nodule in subcutaneous tissue (×2.5); e. ACT-evidence of invasion at the lobular front (×2.5); f. ACT-chondrocytes with moderate cytonuclear atypia (×5).

All patients demonstrated favorable postoperative evolution, with no local recurrence or infection. At three months, complete wound healing and stable osteosynthesis were noted in all cases.

By six months, radiographic evaluation confirmed structural integrity and bone consolidation, with preserved joint mobility and satisfactory aesthetic appearance (tab. IV).

The mean DASH score at final follow-up was 8.4 ± 3.2, indicating minimal disa-

bility. The range of motion (ROM) recovery ranged between 80-100% compared to the contralateral side, and the mean VAS pain score at six months was 1.2/10. Patient satisfaction, both functional and aesthetic, was uniformly high. In the patient diagnosed with Ollier disease, psychiatric therapy was maintained throughout hospitalization under the supervision of the consulting specialist. The patient was discharged with a recommendation for reevaluation after three months; however, follow-up was not achieved due to financial constraints.

TABLE IV.
Outcomes and Follow-up

Outcome parameter	Findings
Follow-up duration	2 years
3-month outcomes	Favorable in all cases; wound healing complete; no infection or recurrence
6-month outcomes	Stable bone structure, no recurrence; good joint mobility
DASH score (mean ± SD)	8.4 ± 3.2 (indicative of minimal disability)
ROM recovery	80-100% compared to contralateral side
VAS pain score at 6 months	Mean 1.2/10
Patient satisfaction (subjective)	High in all cases (no aesthetic complaints)
Psychiatric follow-up (Ollier case)	Maintained during hospitalization; follow-up lost due to financial constraints

DISCUSSION

Solitary enchondroma represents the most common benign cartilaginous tumor of the hand, typically arising from residual chondrocytes of the physeal plate. Although histologically benign, its clinical behavior and radiological appearance may mimic low-grade chondrosarcoma, particularly in cases with cortical expansion or endosteal scalloping. The true incidence of enchondroma is likely underestimated, as many lesions remain asymptomatic and are discovered incidentally during imaging performed for unrelated reasons. In the present series, 13 of 14 patients (92.9%) were diagnosed with solitary enchondroma, most frequently involving the phalanges—an observation consistent with previous reports indicating a predilection for the small tubular bones of the hand (1-3). The phalanges, particularly the proximal and middle segments of the ulnar digits, are known sites of increased enchondral ossification activity, which may explain the predominance of these locations.

Clinically, most patients presented with slowly progressive, painless swelling or localized deformity, in agreement with findings from Kuur and associates (4), who emphasized the insidious nature of the lesion. In this cohort, pain was not a presenting symptom in any case, and functional limitation was minimal prior to surgical intervention. In five cases, however, patients presented to the emergency department with pathological fractures following minor trauma—a typical manifestation of enchondroma-related bone fragility. Radiographically, all lesions appeared as well-defined lytic areas with cortical preservation and variable intralesional calcifications, consistent with the classical imaging features described in the literature (5). Advanced imaging such as CT or MRI is

generally reserved for cases where the extent of cortical involvement or suspicion of malignancy must be clarified. Surgical curettage remains the standard of care for solitary enchondromas of the hand, as it effectively removes the lesion while preserving the structural and functional integrity of the digit. In the present study, all patients underwent intralesional curettage, followed by reconstruction of the residual bone cavity using either autologous cancellous bone graft or a solid bone substitute. Autologous bone grafts were preferred in younger patients with smaller defects, while substitutes were used in larger lesions to minimize donor-site morbidity. These findings align with the observations of Gaulke et al. (6), who reported comparable consolidation times and recurrence rates between autologous grafts and synthetic substitutes. Osteosynthesis was required in nearly all cases to restore mechanical stability after curettage. No postoperative complications or recurrences were recorded during the two-year follow-up period, confirming the efficacy of this surgical approach. The functional outcomes, as measured by DASH and ROM scores, were excellent across the cohort, with a mean DASH score of 8.4 and pain scores approaching zero at six months.

Overall, the outcomes reported in this series reinforce the current understanding that solitary enchondromas of the hand, when managed by meticulous curettage and appropriate reconstruction, have a benign course, excellent functional recovery, and negligible risk of recurrence or malignant transformation. An association between Ollier disease and mutations in the parathyroid hormone receptor 1 (PTHR1) gene, was proposed, particularly the R150C variant, which alters signaling pathways regulating chondrocyte proliferation. Subsequently, in 2011, Amary et al. identified somatic mosaic mutations in the IDH1 and IDH2 genes—encoding isocitrate dehydrogenase enzymes - as central to the disease mechanism (5, 14). These mutations result in aberrant production of D-2-hydroxyglutarate, an oncometabolite that interferes with normal epigenetic regulation, leading to disorganized endochondral ossification, abnormal chondrocyte differentiation, and increased tumorigenic potential (5, 15). Clinically, Ollier disease presents with pain, swelling, and visible deformities, most frequently affecting the hands and lower limbs, often accompanied by limb-length discrepancies resulting from asymmetric skeletal growth. The condition typically progresses slowly; however, the cumulative effects of multiple enchondromas may lead to severe functional impairment, skeletal deformity, and aesthetic disfigurement, profoundly impacting daily activity and psychological well-being (16, 17). Pathological fractures are common, particularly in long bones weakened by extensive enchondromatous replacement (18). The bilateral distribution of lesions in the hands, as seen in this case, is particularly unusual, since Ollier disease typically exhibits unilateral or asymmetrical involvement. Bilateral disease likely reflects a broader embryonic distribution of the somatic mutation, suggesting that the genetic alteration occurred earlier during embryogenesis, giving rise to a wider population of affected mesenchymal progenitor cells. This mechanism may explain the multifocal and systemic pattern observed in this patient, involving not only the hands but also the radius, humerus, scapula, and notably the vomer bone (19, 20). In the present case, the

enchondromatous masses were large, producing extensive bone destruction, with CT imaging revealing near-complete resorption of the phalanges. The disease course is chronic and unpredictable, marked by alternating periods of relative stability and episodes of accelerated lesion growth that may herald incipient malignant transformation. In the reported case, histopathological examination of the amputated segment revealed malignant changes within the enchondroma, consistent with transformation into an atypical cartilaginous tumor (ACT).

The craniofacial localization of an enchondroma in the vomer bone represents an exceptional and clinically significant finding. Enchondromatous lesions in cranial bones are exceedingly rare, with only a handful of cases reported in the literature. Their presence challenges the conventional understanding of the anatomical and embryological boundaries of endochondral ossification, suggesting a wider reach of the somatic mosaicism underlying the disease. The involvement of a flat skull-base bone, such as the vomer, supports the hypothesis that Ollier disease can manifest in nontraditional skeletal regions derived from endochondral ossification centers, including the sphenoid, occipital, and vomer bones. Craniofacial involvement may further complicate the clinical course by producing neurological or otorhinolaryngological manifestations, such as nasal obstruction, sinonasal expansion, or, in rare cases, intracranial extension. In this patient, however, the vomer lesion was entirely asymptomatic, discovered incidentally on CT imaging without associated nasal or sinus manifestations. This rare presentation broadens the current understanding of Ollier disease, reinforcing its multisystemic and mosaic nature and emphasizing the importance of comprehensive imaging evaluation in detecting atypical skeletal localizations that might otherwise remain clinically silent (21, 22).

The surgical management of Ollier disease remains challenging and somewhat controversial. While curettage and bone grafting may be effective for localized lesions, extensive or multifocal disease significantly limits reconstructive potential. Amputation, although radical, may be justified in cases of massive deformity, functional loss, or histologically confirmed malignant transformation. In the present case, amputation of the affected digit provided rapid functional improvement, with no postoperative complications, underscoring the importance of individualized, function-oriented management rather than strict anatomical preservation (23).

Beyond orthopedic considerations, Ollier disease exerts a profound psychological impact. The combination of visible deformities, chronic pain, and recurrent hospitalizations leads to marked emotional distress, particularly in patients diagnosed during childhood (24, 25). The current case illustrates the cumulative psychosocial burden associated with the disease: early-life trauma, together with persistent physical disfigurement and repeated medical interventions, contributed to the development of chronic depression, anxiety, and organic personality disorder. Similar reports in the literature describe the emotional strain of chronic deformity and disability, but few documents psychiatric morbidity of this intensity (26-28).

The literature describes cases of multifocal disease with cranial extension, yet none report such severe psychiatric comorbidity, highlighting the unique multidimen-

sional complexity of the present case—where skeletal deformity, oncologic risk, and psychological decline intersect in a single, rare clinical scenario.

CONCLUSIONS

Ollier disease imposes a profound functional and psychosocial burden on affected individuals. Progressive skeletal deformities of the hands result in substantial loss of dexterity, compromised grasping ability, and a marked decline in overall quality of life. However, the psychological consequences of the disorder often surpass its physical manifestations. Chronic disfigurement, prolonged hospitalization, and persistent social stigmatization contribute to severe emotional distress, manifesting as anxiety, depressive episodes, and long-term psychological exhaustion.

These findings underscore the necessity of a multidisciplinary approach that integrates surgical management with continuous psychological and social support, aimed at optimizing both functional outcomes and mental well-being.

PERINATAL PROFILE OF INFANTS DIAGNOSED WITH CONGENITAL HEART DISEASE: A HOSPITAL-BASED COHORT STUDY (Abstract): Congenital heart disease (CHD) is the most common congenital anomaly worldwide and remains associated with significant neonatal morbidity. Perinatal factors such as prematurity and low birth weight may influence immediate clinical outcomes. This study **aimed** to describe the perinatal characteristics of children diagnosed with CHD in a level I regional hospital. **Materials and methods:** This retrospective descriptive study included children with confirmed CHD diagnosed between 2017-2023. CHD cases were classified into left-to-right shunt lesions, right-to-left shunt lesions, obstructive malformations, and complex CHD. Extracted perinatal variables included sex, gestational age, prematurity categories, birth weight, Apgar scores at 1 and 5 minutes, and mode of delivery. Data are presented as mean ± SD or number (percentage). **Results:** A total of 138 children were included, 50.72% of whom were male. The mean gestational age was 36.37±2.75weeks, with 49 (35.51%) born preterm. Mean birth weight was 2692.55 ± 865.11 g, and low birth weight was observed in 50 (36.23%). Cesarean delivery occurred in 80 (60.10%) of cases. The highest proportions of CHD subtype were observed for complex lesions (28.99%) and right-to-left shunt defects (30.43%). **Conclusions:** This cohort demonstrates a notable burden of prematurity and reduced birth weight in the context of a high proportion of hemodynamically significant CHD. These findings underscore the importance of coordinated perinatal care and highlight the value of regional epidemiological data for informed healthcare planning. **Keywords:** PERINATAL, CONGENITAL HEART DISEASE, COHORT STUDY.

INTRODUCTION

Congenital heart disease (CHD) is among the most common congenital anomalies, affecting approximately 0.8% to 1.2% of live births worldwide (1, 2). In 2021, over 4.18 million children under five years were living with CHD globally, representing a 3.4% increase since 1990 (3).

Despite significant advances in cardiovascular care and surgery have significantly improved survival, CHD remains the leading cause of mortality among congenital defects and continues to impose a substantial global health burden (1, 4). Early diagnosis and appropriate management are essential, as untreated severe CHD may lead to heart failure, growth impairment, and early death (5, 6), while long-term complications such as arrhythmias or heart failure often require ongoing follow-up (7).

The etiology of CHD is multifactorial, involving genetic and environmental determinants (8, 9). Beyond structural cardiac abnormalities, increasing attention has been directed toward the perinatal profile of affected infants. Previous studies have suggested associations between CHD and adverse perinatal characteristics, including prematurity and reduced birth weight, potentially reflecting altered intrauterine development or shared pathophysiological mechanisms (10, 11).

Most data derive from large international registries, whereas regional evidence remains limited, particularly in Eastern Europe, where socio-economic and parental profiles may differ. Regional analyses are important, as healthcare organization, prenatal screening practices, and obstetric management may influence perinatal patterns.

The **aim** of this study was to describe the perinatal characteristics of children diagnosed with CHD in a level I regional hospital and to examine the distribution of major CHD subtypes within this population.

MATERIALS AND METHODS

This retrospective descriptive study was conducted in the neonatal unit of a level I regional hospital and included all children diagnosed with CHD during the study period 2017-2023. The diagnosis of CHD was confirmed by transthoracic echocardiography performed by the same doctor. CHD cases were classified into four major subtypes: left-to-right shunt lesions, right-to-left shunt lesions, obstructive malformations, and complex CHD. Left-to-right shunt lesions included defects such as ventricular septal defect, atrial septal defect, and patent ductus arteriosus. Right-to-left shunt lesions included cyanotic defects associated with reduced pulmonary oxygenation, such as tetralogy of Fallot and transposition physiology. Obstructive lesions included aortic or pulmonary outflow tract obstruction, while complex CHD comprised multiple structural abnormalities with major hemodynamic impact. Perinatal variables extracted from medical records included sex, gestational age at birth, prematurity status, prematurity categories, birth weight, Apgar score at 1 and 5 minutes, and mode of delivery. Low birth weight was defined as <2500 g, and prematurity categories were defined according to standard obstetric criteria. Data were analyzed using descriptive statistics, with continuous variables presented as mean ± standard deviation (SD) and categorical variables as number and percentage. The study was approved by both the Ethics Committee of Grigore T. Popa University of Medicine and Pharmacy, Iasi, Romania (approval number: 640/23.09.2025) and Cuza-Vodă Clinical Hospital of Obstetrics and Gynecology, Iași, Romania (approval number: 5/10.02.2025) before the beginning of the study.

RESULTS

Perinatal characteristics. A total of 138 neonates with CHD were included in

the study. Among them, 68 (49.28 %) were female and 70 (50.72%) were male. Regarding the place of residence, 43 (31.61%) of patients originated from urban areas and 95 (68.84%) from rural areas. The mean gestational age at birth was 36.93±2.59 weeks. Mean birth weight was 2692.55 ± 865.11 g, with a low birth weight (<2500 g) was observed in 50 (36.23%) of patients. The mean Apgar score was 7.05±1.63 (1-9) at one minute, increasing to 7.70±1.40 (0-9) at 5 minutes (tab. I).

TABLE I.
Perinatal characteristics

Perinatal characteristics	Female (n=68)	Male (n=70)	Total (n=138)
Environment			
Rural	48 (70.59%)	47 (67.14%)	95 (68.84%)
Urban	20 (29.41%)	23 (32.86%)	43 (31.16%)
Gestational age (w)	36.37±2.75	37.47±2.31	36.93±2.59
Birth weight (g)	2472.67 ± 855.42	2909.14 ± 825.54	2692.55 ± 865.11
Apgar score			
1 minute	6.76±1.77	7.33±1.41	7.05±1.63 (1-9)
5 minutes	7.44±1.59	7.96±1.11	7.70±1.40 (0-9)

n-number; w - weeks, g - grams

Overall, 89 (64.49%) were born at term, while n=49 (35.51%) were born prematurely. Sex distribution across prematurity categories is detailed in second table.

TABLE III.
Prematurity categories

Prematurity	Female: n=29 (40.8%)	Male n=20 (59.18%)	Total (n=49)
Extremely preterm (<28w)	1 (3.45%)	0 (0%)	1 (2.04%)
Very preterm (28-32 w)	5 (17.24%)	2 (10.00%)	7 (14.29%)
Moderately preterm (32-34w)	2 (6.90%)	2 (10.00%)	4 (8.16%)
Late preterm (34-37w)	21 (72.41%)	16 (80.00%)	37 (75.51%)

n- number, w- weeks

Delivery occurred by cesarean section in 60.10% of cases (n=80), while 39.9% (n=55) were delivered vaginally. Prenatal diagnosis of CHD was established in 20.29% of cases, at a mean gestational age of 24.1 weeks. Most cases were diagnosed postnatally, highlighting the limited prenatal detection rate in the studied population.

CHD subtype distribution. Overall, CHD cases were classified as left-to-right shunt lesions, right-to-left shunt lesions, obstructive lesions, or complex CHD (tab. III).

TABLE IIIII.
Congenital heart disease subtype

CHD subtype	Total
Left-to-right shunt	25 (18.12%)
Right-to-left shunt	41 (30.43%)
Obstructive	32 (23.19%)
Complex CHD	40 (28.99%)

CHD - congenital heart disease

DISCUSSION

The predominance of complex CHD and right-to-left shunt lesions in our cohort suggests a relatively high burden of hemodynamically significant cardiac pathology. These defects are commonly associated with impaired systemic oxygen delivery, respiratory instability, and increased need for specialized neonatal care. In contrast, left-to-right shunt lesions are often better tolerated during the immediate neonatal transition, depending on defect size and pulmonary vascular adaptation.

This study provides a description of perinatal characteristics among children diagnosed with CHD in a level I regional hospital. Given that CHD affects approximately 0.8-1.2% of live births worldwide (12) and remains a leading contributor to congenital morbidity despite advances in care (3), understanding early-life parameters in affected neonates remains clinically meaningful.

Complex congenital heart defects accounted for 28.99%, of cases in our cohort, while right-to-left shunt lesions represented 30.43%, together comprising a substantial proportion of hemodynamically significant anomalies. Such defects are frequently associated with altered systemic oxygen delivery and increased risk of circulatory instability in the early postnatal period.

This subtype distribution provides a physiological context for understanding the modestly reduced mean Apgar scores observed at 1 and 5 minutes, which were slightly below values reported in the general neonatal population according to World Health Organization data (WHO) (13).

Although Apgar score reflects overall neonatal adaptation, rather than isolated cardiac function, transitional challenges are particularly relevant in infants with CHD. The immediate postnatal period requires rapid physiological changes, including functional closure of the ductus arteriosus and *foramen ovale*, a marked decrease in pulmonary vascular resistance, and establishment of effective pulmonary blood flow (14, 15). In neonates with structural cardiac defects, particularly those involving altered shunt physiology or compromised systemic or pulmonary perfusion, these transitional processes may be less efficient. In preterm infants, delayed ductal closure may further aggravate abnormal shunt dynamics, especially when respiratory support such as surfactant therapy or inhaled nitric oxide is required, thereby contributing to transitional hemodynamic instability (10, 16, 17). Impaired systemic oxygen delivery, transient hypoxemia, or reduced cardiac output during this critical transitional period may partially explain the modestly lower early adaptation scores observed in our cohort

(10). Although the descriptive design of this study does not allow for causal conclusions to be drawn, the slightly reduced mean Apgar values may nonetheless reflect a degree of hemodynamic vulnerability during the immediate neonatal transition in infants with CHD.

Prematurity was observed in 35.51% of the cohort, a proportion considerably higher than rates typically reported in the general neonatal population (18)**.** The association between CHD and preterm birth has been previously described and is thought to be multifactorial, involving placental dysfunction, altered fetal hemodynamics, and shared developmental pathways influencing both cardiac morphogenesis and gestational duration (10, 11). In our cohort, the substantial proportion of complex (30.43%) and right-to-left shunt lesions (28.99%) suggests a predominance of hemodynamically significant defects and even early deliver. Prematurity may, in turn, exacerbate postnatal adaptation challenges, as immature myocardial function, delayed ductal closure, and persistent pulmonary vascular resistance can amplify shunt imbalance and transitional instability (14, 16).

Birth weight patterns also align with this vulnerability profile. Infants with CHD are frequently reported to have lower birth weight compared to the general population (11,19). However, while structural cardiac anomalies can influence fetal hemodynamics, potentially influencing intrauterine growth, the relatively high rate of prematurity in our cohort, may have also contributed to the lower mean birth weight.

The cesarean delivery rate observed in our cohort should be interpreted within the broader context of contemporary obstetric practice. Over recent decades, cesarean section rates have increased globally, in many settings exceeding the levels considered optimal by the WHO(13). Pregnancies complicated by suspected or confirmed fetal anomalies, including CHD, are more frequently managed through planned cesarean delivery to allow controlled timing of birth and immediate access to specialized neonatal and cardiology care (14). The relatively low prenatal detection rate observed in our cohort may partially explain the elevated proportion of urgent neonatal evaluations and the variability in delivery practices. Limited prenatal screening accessibility, particularly in rural areas, may contribute to delayed diagnosis and reduced opportunities for planned multidisciplinary perinatal management. While cesarean delivery may facilitate coordinated perinatal management in selected high-risk cases, its increased prevalence also reflects broader trends in modern obstetric practice. As such, the elevated cesarean rate in this cohort likely represents a combination of clinical indication and contemporary delivery patterns.

Beyond their direct clinical implications, these findings also carry important health system relevance. The growing lifetime prevalence of CHD has substantial implications for healthcare planning and long-term resource allocation (20). International scientific statements emphasize the importance of structured, regionally coordinated care pathways to reduce morbidity and improve outcomes (21). However, most epidemiological data derive from large registries(2,6), and regional variability in perinatal patterns is often insufficiently characterized.

Regional cohort-based analyses, such as the present study, provide essential context-specific evidence. Differences in prematurity distribution, birth weight pro-

files, and delivery practices may reflect variations in obstetric management, prenatal screening accessibility, or healthcare infrastructure. Integrating such localized data into larger national frameworks can support differentiated health policy development, including targeted maternal-fetal surveillance programs, optimized neonatal intensive care resource allocation, and regionally adapted referral networks. In this regard, regional epidemiological studies represent a critical component of evidence-based CHD planning.

Strengths and limitations. The strengths of this study include the evaluation of perinatal parameters in a clearly defined cohort and the classification of CHD subtypes. The high proportion of complex and right-to-left shunt lesions provides an important clinical context for interpreting the observed patterns of perinatal vulnerability, including prematurity and reduced birth weight.

However, the retrospective design limits causal interpretation and does not allow differentiation between the independent effects of prematurity and CHD-related intrauterine growth alterations on birth weight. The absence of a control group limits direct comparison with background population rates.

CONCLUSIONS

This study outlines the perinatal profile of children with CHD in a level I regional hospital, highlighting a notable burden of prematurity and reduced birth weight in the context of a high proportion of hemodynamically significant lesions. The coexistence of complex and right-to-left defects with early-life vulnerability parameters suggests increased cardiovascular demands during the immediate neonatal transition. While causal relationships cannot be established, these findings underscore the importance of coordinated obstetric and neonatal management in pregnancies complicated by CHD.

Beyond their clinical implications, regional cohort-based data contribute valuable insight for healthcare planning. As the population living with CHD continues to expand, locally generated epidemiological evidence may support differentiated resource allocation and region-specific perinatal care strategies within broader national health frameworks.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest and they received no funding regarding this scientific research.

SOCIO-DEMOGRAPHIC CHARACTERISTICS AND REPORTED PSYCHO-MEDICAL SYMPTOMS FOR CHILDREN WITH RARE DISEASES. A COMPARATIVE STUDY BETWEEN PATIENTS WITH PHENYLKETONURIA, CYSTIC FIBROSIS AND HYPOTHYROIDISM (Abstract). Rare diseases have great impact on both patients and family members' life. **The aim** of the study was to identify socio-demographic characteristics and factors related to psychological and medical condition for pediatric patients diagnosed with phenylketonuria, cystic fibrosis and hypothyroidism. **Material and methods**: 37 children (24 boys and 13 girls) aged M = 7.61 ± 6.37 (1-22-years-old) were included in the research. A total of 44.7% are diagnosed with cystic fibrosis, 31.6% with phenylketonuria and 23.7% with hypothyroidism. Socio-demographic characteristics and psychological and medical data reported by mothers were registered to point the presence of some characteristics related to the diseases and to identify differences between the three categories of patients. Data have been processed using *SPSS Statistics v23.0.0* for MAC.OSX. **Results**: Almost 1/5 of children diagnosed with hypothyroidism and phenylketonuria were found to have depression symptoms and 1/3 of patients with hypothyroidism are having cognitive impairment associated in 40% of cases with language difficulties, and 20% of them present difficulties to adapt to social environment. A total of 18.3% of children with cystic fibrosis presented enuresis and 20% of them has bruxism. **Conclusions**: children with rare disease present several psychological symptoms and social difficulties, psychotherapeutically and educational support for both patients and families are needed. **Keywords**: CHILD, CYSTIC FIBROSIS, HYPOTHYROIDISM, PHENYL-KETONURIA.

A disease is considered rare when it affects one person out of 2,000 or less. They are between 5,000 and 8,000 rare diseases, most of them genetic. A rare disease is, according to the definition of World Health Organization (1), a life-threatening or chronically debilitating condition from which not more than 5% of citizens in the European Community suffer. It is estimated that 30 million Europeans and 25 million Americans are suffering from a rare disease that coincide with 6-8% of the total popula-

tion (2).

As WHO guidelines, there is a strong recommendation to sustain and develop research in this area to help knowledge about rare diseases and to improve quality of life of patients suffering from orphan diseases. Social support should not be neglected also, *EURORDIS Care Survey Program* conducted in 23 countries between 2004-2004 included 12,000 patients with rare diseases (3). The survey concluded that "social security systems are usually designed around common diseases are not flexible enough to take into consideration unprecedented health need" as is an orphan disease.

Some diseases are more frequent and programs are already implemented in many countries.

Phenylketonuria (PKU) is a rare metabolic disease that has consequences on cognitive development. The cognitive impairment appears if the patient is not treated with a strict protein-restricted diet. Even with early diagnosis and treatment of PKU children, these patients present some deficiencies intellectually compared to normal children (4). Following the medical recommendation regarding diet are extremely important for medical development of the disease and for the quality of life of patient. In many cases, diet and its restrictions are the most stressful factor for parents having a child diagnosed with this disease and perceived social support and diagnosis resolutions seems to improve coping strategies and quality of life for caregivers (5, 6). Some studies assessing the occurrence of psychiatric disorders identified in patients with early treatment for PKU a high rate of anxiety disorder and the tendency of withdrawal were mentioned being the most frequent self-reported symptoms. A study of Manti *et al*. (7) showed that patients with good metabolic control in the first eleven years of life proved higher frequency of psychiatric diagnosis comparing to those having more years from diagnosis, meaning that respecting diet represents a distressful situation and children or adolescents are feeling more frustrating. Psychological and psychiatric evaluation is recommended for all children under medical treatment.

Cystic fibrosis (CF) is a genetic disease of the exocrine glands that affects all races but primarily whites. For this reason, since 2001, the American College of Obstetricians and Gynecologists recommends that white women be tested for the gene if they are pregnant or considering pregnancy (8) and three years later, in 2004, the Centers for Disease Control and Prevention (CDC) published their pivotal recommendation that regions "begin newborn screening for CF" (9, 10). A patient with CF and members of the family may have tremendous physical, psychosocial, and educational needs. As the patient get older, some new problems may arise or existing problems may worsen requiring comprehensive, multidisciplinary lifelong care (11). Sometimes patients with CF could be misdiagnosed earlier in life as having asthma or chronic bronchitis.

Hypothyroidism can manifest with different signs and symptoms. In the pediatric population, the prevalence of this thyroid disorder is estimated to be less than 10% (12). This disorder has a wide range of presentation from subclinical hypothyroidism to overt form. Hearing loss is more common in hypothyroid patients than normal population so diagnosing earlier the deafness will help children to be cognitively stimulated. Dental problems and cardiac

manifestations need also to be identified to improve quality of life for these patients.

Living with these rare diseases demand a lot of effort of family members, multidisciplinary team and a strong determination to empower the patient (if possible) to care about own medical and psychological problems. Early diagnosis, adherence to treatment, family, medical and social support are important for a high level of quality of life. The care for the patients must be doubled by the care for the family members to improve life standards for all persons touched by the diseases.

In the majority of cases, mothers are the carrier of children with a rare disease. One of the most common behavior identified in mothers having a child with a rare disease is the hyper-protection, attitude with a negative impact over the years, causing a lot of reactiveness in children during their pre/adolescence period. That is why mothers or caregivers must be well trained to help, supervise, interfere and treat their children.

The aim of this study is to identify psychological and medical symptoms of pediatric patients suffering from these three rare diseases (cystic fibrosis, hypothyroidism and phenylketonuria) as that are declared by their mothers.

MATERIAL AND METHODS

A number of 37 patients aged 1-22 years old were included in the study (M = 7.61 ± 6.37). In Romania, patients older than 18 are continuing to be hospitalized in pediatric clinics till the age of 25 if they are registered in the educational system. The children were diagnosed and under medical supervision in "Saint Mary" Emergency University Hospital for Children in Iasi, Romania with one of the following three rare disease: cystic fibrosis, hypothyroidism and phenylketonuria.

The study has been approved by the Ethical Committee of "Sf. Maria" Emergency Clinical Hospital for Children and questioned mothers and children were informed about the confidentiality and use of data and results and mothers signed an informed consent before filling in the items.

Socio-demographic and family member's information (age for patient and both parents, sex, religion, department, environment and level of education for both parents) were registered. The mothers of the patients had to indicate psychological, social and physical symptoms that they have been identified to their children.

Statistical analysis was performed using *SPSS Statistics version 23.0.0* for MAC. OSX.

RESULTS AND DISCUSSION

Descriptive statistics – general results

The socio-demographic and self-reported data were gathered during their hospitalizations from 2016. For 24 boys and 13 girls hospitalized in 2016, mothers reported psychological and medical symptoms for their children and appreciated their social interactions with peers. More than half of the patients (69.4%) are aged between 2 and 6 years old, 27.8% are aged between 6 and 12 years old, and the rest (2.8%) are older than 12 years old.

The patients are coming from 6 districts of North-eastern part of the country (Bacau, Botosani, Iasi, Neamt, Suceava, Vaslui), 17 of patients (45.95%) living in urban area and 20 (54.05%) living in countryside. The distribution of patients considering their gender and disease is presented in Table I.

TABLE I.

Data referring to the distribution of patients accordingly to disease, gender and age at diagnostics

Disease	Male	Female	Age at diagnostic (M ± SDV)
Phenylketonuria	10 (41.7%)	1 (7.7%)	M = 1.12 ± 1.24 months
Hypothyroidism	3 (12.5%)	6 (46.2%)	M = 1.66 ± 0.70 months
Cystic fibrosis	11 (45.8%)	6 (46.2%)	M = 20.58 ± 34.71 months

Family data

Mothers were asked about their marital situation at the time of diagnosis and 25 of them (67.57%) declared that they were married. Eleven of them (32.35%) are having one child, 18 (52.94%) are having 2 children, 3 (8.82%) are having 3 children and 2 (5.88%) are having 4 children (the number of births/mother is M = 2 ± 0.76).

Data about the religion of the family members revealed that the majority patients are Orthodox-Christian (92.1%), and a small number is Pentecostal (5.3%) and Adventist (2.6%).

The minimum age of mothers is 18 and the maximum is 55 years old (M = 33.05 ± 8.52). For the fathers, the minimum age is 21 and the maximum is 56 years old (M = 37.87 ± 7.79).

Data regarding the educational level of parents was also registered. A total of 6.1% of the mothers have primary education background, 21.2% gymnasium level, 57.6% have reached high school level, and 15.2% graduated college. In what concern the level of education of fathers, 5.7% have primary education background, 22.9% gymnasium level, 68.6% have reached high school level, and 2.9% graduated college.

TABLE II.

The distribution of patients accordingly to their age

Age	1	2	3	4	5	7	8	11	12	13	16	19	20	21	22
N	2	5	6	4	4	1	3	1	3	1	1	2	1	1	1
%	5.6	13.5	16.2	10.8	10.8	2.7	8.1	2.7	8.1	2.7	2.7	5.4	2.7	2.7	2.7

Patients with phenylketonuria

The minimum registered age at diagnosis for this category of pediatric patients is 0 months (3 weeks) and the maximum is 4 months, with a mean of 1.12 ± 1.24 months. In the case of *phenylketonuria* none of the patients (with M =3.36 ± 3.29, minimum age of 1 year old and maximum age of 13 years old) displayed loss of appetite, bowel movement problems, muscular dystrophy, intellectual disability, bradypsychia, language difficulties, memory difficulties, unhealthy behaviors, bruxism, night terrors, bed wetting, behavioral problems, isolation (by others or themselves), panic attacks, or a high caloric diet. 40% of the patients presented nutritional problems and 40% of the patients presented sleep-related problems. Most them (80%) complied with their treatment.

Considering anger outbursts, 25% of the patients had them, and more than half of the patients (60%) were advised on a nutrition diet. 20% of the children had depression, and more than half of the patients (66.7%) followed nutritional recommendation.

Patients with hypothyroidism

The minimum registered age at diagnosis for this category of disease is at birth (more frequent is the third week of life) and the maximum is 3 months, with a mean of 1.66 ± 0.70 months. The age at the time of the study is M =3.62 ± 1.68, with a minimum age of 1 and a maximum age of 7. In the case of *hypothyroidism*, patients did not display bowel movement problems, muscular dystrophy, bradypsychia, and memory difficulties, nutrition problems, bruxism, night terrors, bed wetting, behavioral problems, panic attacks or a high caloric diet. In case of 16.7% we identified a loss of appetite, and 33.3% presented intellectual disability. Almost 40% of the patients had language problems and 20% of the patients displayed unhealthy behaviors. In case of 16.7% of the patients, mothers reported sleep problems.

In case of 20% of the patients, mothers were reported having depressive symptoms. More than half of the patients (60%) complied with their treatment and 83.3% were taking medication. 20% of the patients experienced isolation (by others or themselves) and 20% of the patients displayed anger outbursts. Half of the patients were advised on a diet. Many of the patients (80%) followed their nutritional recommendations.

Our findings are congruent to the scientific data from the literature. Findings published by Rovet and Ehrlich (13) indicated cognitive problems for children with hypothyroidism that persist into adolescence (memory, attention, or visual and spatial processing areas). For these problems, the educational support is extremely important, to supervise medical condition, intellectual achievement and behavior.

In our study, mothers identified in case of 20% that children suffering from hypothyroidism are having depression symptoms, angriness and unhealthy behaviors and isolation. Their physical aspect, the cognitive impairment, language problems and motor skills (14, 15) are factors that influence their social interaction and family members and teachers must be informed about these aspects to diminish the child's distress. Social and educational difficulties should not be underestimated, as the scientific results are proving that physical condition is usually more supervised and cared compared to psychological and social well-being (16, 17). Despite the results presented by many researches referring to the negative cognitive development in case of under-treatment, few studies have been focused on the effects of overtreatment of patients with this disease. A study of Bongers-Schokking (18) shows that overtreatment during the first two years determines lower cognitive outcomes (the study being lead on patients aged 11). The authors suggest also that fast TSH normalization at initial treatment leads to above-normal development scores at a young age but does not affect the quotient of intelligence at the age of 11 years.

Patients with cystic fibrosis (CF)

The minimum registered age at diagnosis for this category of disease is at birth (first month) and the maximum is 132 months, with a mean of 20.58 ± 34.71 months. The age at the time of the study is M =12.23±6.13; the minimum registered age is 5 years old the maximum is 22 years old.

The patients diagnosed with CF have no record of bradylalia, memory difficulties, unhealthy behaviors, night terrors, behavioral problems or panic attacks. 23.1% had

a loss of appetite, 66.7% had bowel movements problems, 30.8% had muscular dystrophy and 9.1% presented intellectual disability and bradypsychia.

Most patients suffering from CF present nutritional problems (25%), 10% had sleep problems, 20% present bruxism and 18.2% were diagnosed with enuresis. A small number of pediatric patients (9.1%) presented symptoms of depression.

Almost half of the patients (45.5%) complied with their treatment and large majority of patients (91.7%) took medication.

In case of 7.7% of patients' mothers declared that children experienced isolation and 8.3% of the patients displayed anger outbursts. A percentage of 41.7% from the patients were on a high caloric diet. More than half of the patients (69.2%) were advised on a nutrition diet, and all the patients followed their nutritional recommendations.

Early medical intervention is essential for these patients so neonatal screening is demanded. Understanding the ethical issues in CF is an important factor for providing optimal care of newborn with CF (19). Our results prove that children with CF have an older age at the moment of their diagnostic comparing to the pediatric patients suffering from the other two diseases.

Comparative statistics

Comparative results for the three diseases are presented in Table III. The higher number of symptoms identified by mother are those having children diagnosed with cystic fibrosis.

TABLE III.

Comparative results for variables in phenylketonuria, hypothyroidism and cystic fibrosis

Variables		Phenylketonuria	Hypothyroidism	Cystic fibrosis
Loss of appetite	Yes	0%	**16.7%**	**23.1%**
	No	100%	83.3%	76.9%

Following nutritional recommendations	Yes	**66.7%**	**80%**	**100%**
	No	33.3%	20%	0%

It is important to notice that, regarding the way the patients follow the nutritional recommendations, the rate of affirmative responses is very high, for all three of diseases. This result proves that families understand very well importance of the nutritional diet and respect the medical recommendation to negative effects on child's development. For example, prevention or early treatment of iron deficiency may improve cognitive development and behavior of children with PKU (20). It is important to register from the beginning of the diagnostic family rules for food and nutrition and to identify restriction imposed, for example, by the religious believes. Multidisciplinary counsel is imposed for these medical cases.

Our results reveal psychological symptoms and important factors related to patients suffering from the considered diseases. We found that important rate of pediatric patients questioned are presenting nutritional problems and sleep disturbance (higher rate in phenylketonuria), cognitive impairment (higher rate for hypothyroidism), and enuresis and bowel syndrome (higher rate for cystic fibrosis). Almost 1/5 of children diagnosed with hypothyroidism and phenylketonuria were found to have

depression symptoms, as their mothers declared. The physical and psychological problems seem to be frequent and care for these patients must be done in a multidisciplinary team, as soon as possible after the diagnostic. Personalized educational support plan is required for children having cognitive delay such those with congenital hypothyroidism and hearing tests, memory deficit, speech and visual development must be targeted from the beginning (21).

Study limits. This study has some limitations. The first one is due to the small number of children and comparative study must be treated with precautiousness. The second one is referring to children's age. Some items targeting data, like fertility problems are not available for newborn baby or before the age of puberty. So, comparative results could not be generalized.

CONCLUSIONS

Children with a rare disease present several psychological symptoms and social difficulties that can been identified by the family members, especially mothers who are the most frequent the responsible and dependable caregiver.

The educational support of pediatric patient and psychotherapy intervention for both patients and families are needed as soon as possible after the medical diagnostic. Psychological support must not be neglected or not prioritized due to the medical outcomes.

NANOMEDICINES IN CANCER THERAPY – MICELLAR CYTOCHROME P450 INHIBITORS

Nanomedicines are mainly used as drug delivery systems. Recently was evaluated a new therapeutic possibility of inhibiting a drug's metabolism thereby enhancing its effective dose. Most of the phase I drug metabolism is carried out by the hepatic cytochrome P450 (CYP450) enzymes, which due to genetic polymorphisms leads to high inter-individual variability. Micelles containing the natural furanocoumarin 6′,7′-dihydroxybergamottin (DHB), a known CYP450 inhibitor, were developed and studied for the influence on metabolism and bioavailability of the oncology drug docetaxel. It was observed that the administration of DHB-micelles in mice at 24 h prior to the drug enhanced antitumor efficacy in the tumor xenograft models HT-29 and MDA-MB-231, when compared to the drug alone. The researchers encapsulated in nanocarrier natural compounds, known for their metabolism-blocking capacity and absence of reported toxicity, with intravenous administration for the inhibition of the hepatic metabolism of drugs to enhance the useful dose and/or reduce the ineffective proportion of the dose often responsible for the toxicity of the injected drug. These findings are encouraging in terms of increased efficacy and prolonged overall survival in xenografted murine models with good tolerance to treatment. The preclinical benefit–risk ratio of introducing such a metabolism-blocking agent in association with drugs with a narrow therapeutic window or relying too much on the CYP450 status of patients is under studies. Despite not being optimized in terms of targeting hepatocytes, DHB-micelles represent the first injectable example of nanosized metabolism-blocking agents and open the way for further work on such nanomedicines in man (Paolini M, Poul L, Darmona A, Germain M, Pottier A, Levy L, Vibert E. A new opportunity for nanomedicines: Micellar cytochrome P450 inhibitors to improve drug efficacy in a cancer therapy model. *Nanomedicine: Nanotechnology, Biology, and Medicine* 2017; 13: 1715-1723).

INTERNAL FIXATION WITH HANSSON TWIN HOOK FOR TROCHANTERIC FRACTURES (Abstract): Hansson Twin Hook was recently developed as an alternative to the classical Dynamic Hip Screw. In the present study we aimed at presenting our results obtained by using the HTH in the treatment of trochanteric fractures. **Materials and methods**: Over a 2-year interval, 55 patients with trochanteric fractures were treated by reduction and internal fixation using HTH system. According to the AO fracture classification, we recorded 21 cases of 31.A1 fractures and 34 cases of 31.A2 fractures. **Results**: Clinical assessment at 3 months postoperatively using Merle D'Aubignier scale showed very good results in 41 (82%) patients, good in 7 (14%) patients and poor in 2 (4%) patients (two patients presented fixation failure). In these 2 patients, surgical reintervention was performed -implant removal and its replacement with a Dynamic Condylar Screw with good results at 3 months follow-up. **Conclusions**: Osteosynthesis with Hansson Twin Hook is a good choice in trochanteric fractures. Since it is a new developed implant, more studies are necessary for clinical validation of its value. **Keywords:** TWIN HOOK, TROCHANTERIC FRACTURES, ROTATIONAL STABILITY.

The results of internal fixation in proximal femoral fractures are disappointing in the elderly. Many studies showed a high reintervention rate associated with functional impairment and an increased morbidity of 35 % to 48% (1, 2). Dynamic hip screw (DHS) and short Gamma nail systems are commonly used for internal fixation of trochanteric fractures with favorable clinical outcomes (3). However, 1 to 4% of fractures fixed with DHS and 6-8% of those fixed with short Gamma nail require reintervention for "cut- out" (2).

The Hansson Twin Hook system (HTH) was developed as an alternative to the lag screw in combination with a dynamic plate. It consists of a side-plate combined with a sliding screw from which two apical hooks are deployed in opposite directions - anterior and posterior.

Before clinical use, comparative biomechanical studies of the new Twin Hook system and DHS systems - that rely on lag screw and are now considered "golden standard" in the treatment of trochanteric fractures - were conducted. Both the load

test and angulation and torsion tests revealed that to achieve the same deformation more force is needed for HTH system. These studies recommend HTH system as being biomechanically superior to conventional threaded screw implants. After receiving approval for clinical use, the first study that described its results appeared in 2000 (1); since then, only few studies were published on this topic (4, 5, 6, 7).

In the present study we aimed at presenting our results obtained by using the HTH in the treatment of trochanteric fractures.

MATERIALS AND METHODS

Over a 2-years interval, 55 patients with trochanteric fractures were treated by reduction and internal fixation using HTH system. Age-group distribution showed that most patients (n=20) were in the seventh decade of life (36.3%); mean age was 76 years (range 64-85 years), there was a predominance of female patients (female to male ratio = 36/19) and most patients were from rural areas. According to the AO fracture classification, we recorded 21 (38.2%) cases of 31.A1 fractures (stable trochanteric fractures) and 34 (61,8%) cases of 31.A2 fractures (unstable trochanteric fractures).

Close reduction was performed with the patient positioned on fracture table in all but 6 (10.9%) cases which required open reduction. The femoral head diameter was measured on preoperative X-rays. Incision length, surgery duration, cephalic screw length and femoral plate length were recorded. On anteroposterior and lateral postoperative X-rays, the adequacy of cephalic implant placement was assessed using the quadrants of Baumgaertner and the "tip-apex" distance was measured (8).

Postoperatively, patients were kept in bed for one day, the next day could sit at bedside and the third day resumed walking with the aid of a walker (partial weight-bearing). Patients were assessed clinically and radiographically immediately postoperatively and at 3 months, 6 months, and 1 year. Clinical outcome was assessed using Merle D'Aubignier score.

RESULTS

In our patients the size of femoral head was 42 to 62 mm, with an average of 44.4 mm in women (ranges 42 to 48 mm) and 55.8 mm in men (ranges 52 to 62 mm). The average surgery time was 36 minutes (range 26 to 48 minutes), and average incision length 6 cm (range 4 to 8 cm). The average length of the cephalic implant was 85 mm. Plates with three bicortical screws were used in 41 cases and with 4 bicortical screws in 14 cases (fig. 1).

On anteroposterior and lateral postoperative X-rays, the cephalic implant was in quadrant 5 (quadrants of Baumgaertner) in all cases but one; "tip-apex" distance had an average of 24.3 mm. The one case in which the implant was placed in the inferior quadrant had a tip-apex distance of 39.7 mm (fig. 2), significantly bigger than the average of all others.

Lateral X-ray view was used in all cases for measuring the distance between the tip of the hook and the joint, both in the anterior and in the posterior direction. There were no cases in which the hook penetrated the joint after expandation; the average distance between the tip of the hook and the joint was 9 mm, with a minimal distance of 2 mm.

At the 3-months postoperative follow up, radiological consolidation of fracture

site was seen in all but 2 (3.63%), patients one presenting femoral variation with a tendency for cephalic implant cut-out (fig. 3), and the other one cephalic implant cut-out, these two cases requiring surgical reintervention. Clinical assessment at 3 months postoperatively for 50 (90.9%) patients using Merle D'Aubignier scale showed very good results in 41 (82%) patients, good in 7 (14%) patients and poor in 2 (4%) patients (the 2 patients with fixation failure). In these 2 (3.63%) patients, surgical reintervention was performed - HTH removal and its replacement with a DCS, with good results at 3 months follow-up.

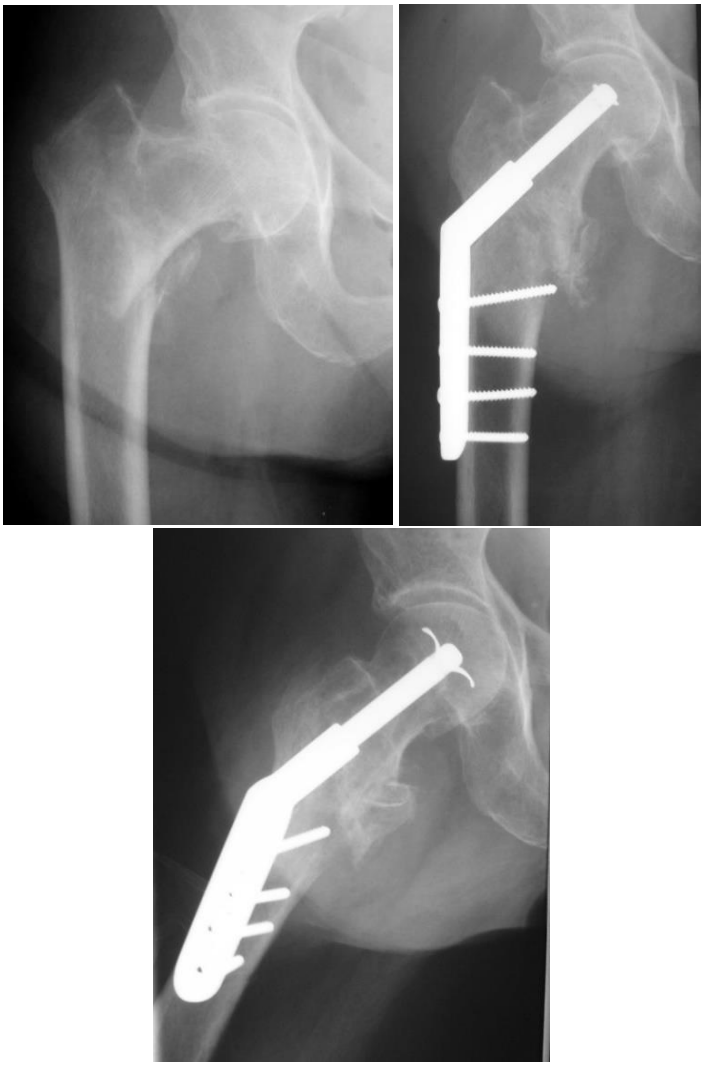

Fig. 1. Internal fixation with Hansson Twin Hook in a trochanteric fracture. Correct positioning of the implant. Preoperative X-ray (A), antero-posterior postoperative X-ray (B), lateral postoperative X-ray (C).

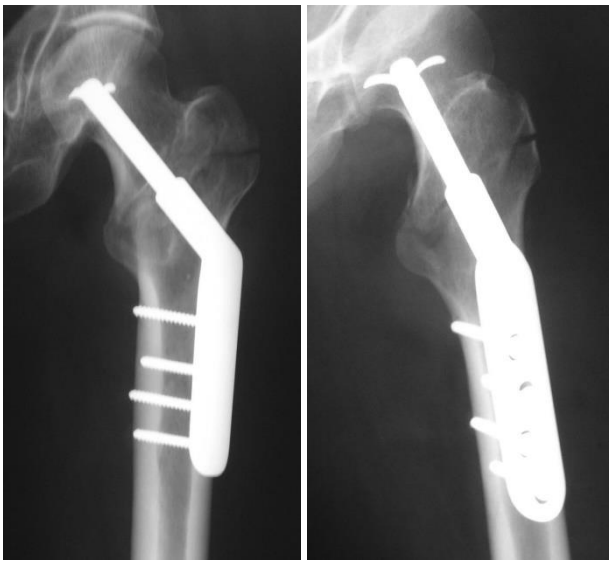

Fig. 2. Internal fixation with Hansson Twin Hook in a trochanteric fracture. Inferior positioning of the implant with a tip-apex distance of 39.7 mm; antero-posterior postoperative X-ray (A), lateral postoperative X-ray (B).

Fig 3. Fixation failure in a 71-year-old patient at 3 months after surgery.

One year after surgery, 37 (67.2%) patients were available for follow-up. For those, the results were very good in 13 (35.1%) patients, good in 20 (54%) patients and poor in 4 (10.9%) patients. In most patients, the results of clinical assessments were not influenced by implant placement - except the two “fixation failure” cases and

fracture type, but rather by general health status and number of associated comorbidities.

DISCUSSION

Osteosynthesis with HTH in trochanteric fractures has recently been proposed and therefore there are very few studies in the literature on the subject. Most studies on this new implant took place in Scandinavian countries where Hansson Hook is traditionally used in femoral neck fractures.

Olsson et al. (5) conducted in 2000 a retrospective study on 102 patients with hip fractures surgically treated using the HTH compared to a classic DHS compression system and Medoff plate (MSP). Technical errors in HTH system insertion occurred intraoperatively in 7 cases, but overall, postoperative failures were equally distributed between the 2 groups. They concluded that HTH system gives adequate fixation comparable to that produced by DHS and MSP. Also in 2000, Olsson (4) conducted a clinical and biomechanical study on 342 trochanteric fractures comparing the resistance and stability of HTH with MSP. He found an enhanced stress resistance with the use of MPS than DHS in intertrochanteric fractures, and comparable stability with the use of MSP and Gamma system in sub trochanteric fractures; in addition, HTH provides enhanced migration resistance under both axial and torsional loading. In 2002, Olsson et al. (6) published another biomechanical study conducted this time in artificial bone comparing HTH and DHS systems; they found that the two implants gave similar fixation in terms of resistance but the degree of impactation at fracture site was superior with HTH.

In 2008, Hagino et al. (9), compared the results obtained by using HTH and DHS systems in terms of technical accuracy: HTH was used in 17 patients, being inserted into the center of femoral with an average tip - apex distance of 22.3 mm; DHS was used in 202 patients with an average tip - apex distance of 14.6 mm. No device failure or cut-out was found. They concluded that using HTH system requires more surgical skill than using DHS, because failure to insert the screw into the center of the femoral head may cause intraarticular perforation by the hooks.

In 2008, Olséen et al. (10) compared the fixation stability of HTH reported by 55 surgeons in 157 elderly patients with trochanteric fractures, 83 % of which were unstable. They found technical intraoperative errors in 7 cases, HTH had not been placed centrally in the femoral head, of these only two presenting fixation failures at the 2-year follow-up; they concluded that HTH system is easy to use, gives adequate fixation in the bone of elderly osteoporotic patients with trochanteric fracture and has a low failure rate.

Roerdink (11) published his study in 2009, starting from the assumption that intracapsular fractures are frequently accompanied by pseudarthrosis and aseptic necrosis of the femoral head performed a comparative biomechanical study in synthetic bone to compare DHS, HTH and dynamic locking blade plate (DLBP). He concluded that HTH system gives a stable fixation with a minimum amount of replaced bone, is a dynamic implant, and its angular and rotational stability is 2 times higher than that of DHS.

CONCLUSIONS

The results of our research have shown that osteosynthesis with Hansson Twin

Hook (HTH) gives a superior biomechanical stability compared to DHS systems and the shorter skin incision results in earlier mobilization, less bleeding and esthetic benefits. HTH is rotationally stable, thus being the ideal implant in basic cervical fractures characterized by an increased tendency to rotate.

In most patients one-year follow-up demonstrated good and very good outcomes. HTH allows less disruption to cancellous bone than conventional DHS systems, thus favoring stability; insertion of cephalic implant is atraumatic, fact of importance in preventing aseptic necrosis of the femoral head. Insertion technique is easy and does not require long-term training especially in surgeons familiar with DHS-type systems; in osteoporotic patients' caution is recommend in using HTH because being less bulky there is a higher risk of articular penetration.

MULTIPLE RISK FACTORS FOR THROMBOEMBOLISM AND PREGNANCY LOSS IN SYSTEMIC LUPUS ERYTHEMATOSUS: A CASE REPORT (Abstract): Systemic Lupus Erythematosus (SLE) is known to pose difficulties when pregnancy is desired. Pregnancy in patients with SLE remains a high risk situation with an increased frequency of fetal loss, preeclampsia, growth restriction and prematurity. We illustrate the case of a young female referred to our clinic by the Institute of Cardiovascular Diseases with a history of miscarriage at 20 weeks of gestation and an episode of pulmonary embolism resulting in multiple peripheral infarctions in the right lung confirmed by spiral CT angiography of the pulmonary arteries. Whereas clinical examination showed no significant changes, routine laboratory assessment confirmed the presence of hemolytic anemia, thrombocytopenia and renal impairment, as well as non-specific inflammatory syndrome. Immunological tests proved positive for the following: antinuclear antibodies, anti-dsDNA antibodies, anti-mitochondrial M2 antibodies, anti-beta2 microglobulin, anti-cardiolipin and lupus anticoagulants. In addition, TPHA and RPR were positive and the C3 fraction of the complement was below normal. Genetic investigations identified the 677 C/T homozygous mutation of the MTFHR gene (Methylenetetrahydrofolate reductase) as well as 675 4G and 844 A/G mutations of the PAI-1 gene (plasminogen activator inhibitor-1). Cases of young female SLE patients positive for the antiphospholipid syndrome remain challenging for clinicians, especially when pregnancy is desired. **Keywords**: LUPUS, PREGNANCY, MISCARRIAGE, THROMBOEMBOLISM.

Systemic lupus erythematosus (SLE) is a chronic autoimmune disease associated with multisystemic involvement and heterogenous clinical manifestations. During pregnancy, it is best that women with SLE have little or no disease activity. However, pregnancy in SLE patients remains a high-risk situation with an increased frequency of fetal loss, preeclampsia, growth restriction and prematurity. The risk for increased disease activity during pregnancy is greater in women who have active SLE in the months prior to conception (1). Pregnant SLE patients also have a greater risk of developing complications. The presence of the antiphospholipid syndrome (APS) was found to associate with pregnancy loss, prematurity, fetal distress,

growth restriction, preeclampsia or eclampsia, fetal neonatal thrombosis, placental insufficiency as well as myocardial infarction, pulmonary embolism and stroke (2).

Epidemiological studies revealed that antiphospholipid (aPL) antibodies are detected in up to 40% of patients with SLE. In aPL-positive SLE patients, pregnancy morbidity is more common (up to 45%) than in aPL-negative women (2). Lupus nephritis is also thought to increase the risk for adverse pregnancy outcome in APS women (1,2).

CASE REPORT

We report the case of a 31-years-old female who was referred to our clinic by the Institute of Cardiovascular Diseases with recent history of pulmonary embolism resulting in multiple peripheral infarctions in the right lung confirmed by spiral CT angiography of the pulmonary arteries. She was diagnosed with APS and treated with both antiplatelet and anticoagulant medication.

Our patient's personal history included active smoker status (7 cigarettes per day for 6 years), miscarriage at 20 weeks of gestation (February 2015) shortly followed by pulmonary embolism. She had no history of substance abuse, alcohol consumption or procoagulant medication.

Clinical examination was normal upon presentation in our service. Routine laboratory tests detected hemolytic anemia, thrombocytopenia (<100,000/mm3) and renal impairment (proteinuria>0,5g/day as well as cellular casts). High levels of inflammatory markers were detected: elevated erythrocyte sedimentation rate (ESR) and C reactive protein (CRP). Immunological investigations identified high antibody titers against β2-glycoprotein I (anti-β2GPI) anticardiolipin (aCL) antibodies, lupus anticoagulants, as well as rheumatoid factor (RF), antinuclear antibodies (ANA), anti-double stranded DNA (anti-dsDNA) and antimitochondrial M2 antibodies (AMA M2) (tab. I). The above-mentioned parameters were measured through ELISA. In addition, Treponema Pallidum Haemagglutination Assay (TPHA) and Rapid Plasma Reagin (RPR) were positive and the C3 fraction of the complement was below normal.

TABLE I

Autoantibody titers detected in our patient compared to normal values provided by the laboratory.

Parameter (ELISA)	Value obtained	Reference interval/ Normal values	Measurement unit
Anti-dsDNA antibodies	246.40	0-40	UI/ml
aPL antibodies (IgG)	63.57	Positive >18	U/ml
aPL antibodies (IgM)	26.75	Positive >18	U/ml
Anti-β2GPI antibodies (IgG, IgA, IgM)	37.99	Positive >24	U/ml
aCL antibodies (IgG)	123.65	0-23	GPL/ml
aCL antibodies (IgM)	45.54	0-11	MPL/min
AMA M2	99.74	Positive >24	U/ml
RF	33.94	Positive >24	U/ml
ANA	32.05	0-20	UA/ml

Genetic investigations identified the 677 C/T homozygous mutation of the methylenetetrahydrofolate reductase gene (MTFHR) as well as 675 4G and 844 A/G mutations of the plasminogen activator inhibitor-1 gene (PAI-1).

The patient was consequently diagnosed with systemic lupus erythematosus according to the American College of Rheumatology (ACR) diagnosis criteria for SLE revised in 1997, as well as secondary antiphospholipid syndrome. She started oral treatment with hidroxycloroquine 400 mg/day, azathioprine 100 mg/day, clopidogrel 75 mg/day and acenocumarol under careful monitoring of INR values.

DISCUSSION

In our patient, the new-onset SLE consisted of a miscarriage followed by an episode of pulmonary embolism, which are both indicators of secondary APS. Hematological changes included thrombocytopenia and autoimmune hemolytic anemia (AIHA). The pathogenesis of the latter is closely related to the presence of anti-erythrocyte antibodies. Studies showed an association between anti-cardiolipin antibodies and anti-erythrocyte antibodies (3). Complement regulatory proteins CD55 and CD59 protect against erythrocyte lysis. However, they are under expressed in patients with SLE (4).

Our patient had thrombocytopenia possibly due to increased peripheral destruction mediated by antiplatelet antibodies. Alongside this mechanism, two other phenomena have an important role in the appearance of thrombocytopenia: cell sequestration in the spleen and impaired production in the bone marrow (5).

Secondary antiphospholipid syndrome is a common discovery in patients with SLE. APS symptoms may be the first to appear in certain cases. Our patient fulfilled the 2006 classification criteria for APS (Sydney Consensus Statement on Investigational Classification Criteria for Antiphospholipid Syndrome) (6). The PROMISSE Study (Predictors of pRegnancy Outcome: bioMarkers in antiphospholipid antibody Syndrome and Systemic lupus Erythematosus) showed that patients having high titers of lupus anticoagulant antibodies exhibit high risk for adverse pregnancy outcome (7). Another study (8) supported the role of all three antibodies for predicting obstetric complications such as: recurrent miscarriage, early delivery, oligohydramnios, prematurity, intrauterine growth restriction, fetal distress, fetal or neonatal thrombosis, pre-eclampsia/eclampsia, HELLP syndrome (Hemolysis, Elevated Liver enzymes, Low Platelet count), arterial or venous thrombosis and placental insufficiency.

SLE is characterized by impaired apoptosis. Patients with SLE may develop autoantibodies such as anti-Ro (SSA) and anti-La (SSB) which can cross the placenta causing neonatal lupus (9). Furthermore, anti-dsDNA antibodies may determine miscarriages by inhibiting the migration and attachment of the trophoblast (10).

Our patient exhibited genetic mutations including the 677 C/T homozygous mutation of the MTFHR gene and the 675 4G and 844 A/G mutations of the PAI-1 gene. The PAI-1 675 4G and 844 A/G mutations are associated with high levels of PAI-1 and impaired fibrinolysis. Recent studies have shown that the 844 A/G polymorphism in the PAI-1 gene identified in our patient may be associated with increased risk for osteonecrosis of the femoral head, acute coronary syndrome and venous thromboembolism (11).

Among other important functions, MTFHR is implicated in DNA methylation and the production of signaling molecules which play a role in embryonic development. Female carriers of the 667 C/T homozygous genotype have low estradiol levels, increased anti-Müllerian hormone concentrations and lower oocyte numbers. Normal MTHFR activity ultimately leads to breaking down the amino acid homocysteine. Increased levels of homocysteine were found to be toxic for embryos (12). The appearance of neural tube defects is associated with both heterozygous and homozygous maternal mutations of the MTHFR gene (13). However, the 677 C/T mutation is not thought to be associated with recurrent pregnancy loss in Caucasian women (14).

The presence of lupus nephritis in our patient is also accompanied by a high risk of fetal loss or complications. Optimal management of lupus nephritis is of major importance to prevent SLE-related adverse pregnancy outcome (15).

CONCLUSIONS

We described the case of a young female diagnosed with SLE after a miscarriage followed by an episode of pulmonary embolism. Clinical examination identified no abnormalities, whereas immunological, hematological and genetic modifications were all present. Our patient expressed her desire for safe successful pregnancy. However, antiphospholipid and anti-dsDNA antibody positivity, as well as our patient's genetic background and the presence of lupus nephritis constitute important risk factors for adverse pregnancy outcome. High SLE activity is a contraindication for pregnancy. Patients in remission for at least 6 months before pregnancy have a better prognosis. The postpartum period as well as the second and third trimesters of pregnancy are associated with high risk for SLE flares. The presence of APS in young female SLE patients pose additional challenges for clinicians, especially when pregnancy is desired.

NEWS

LIVER SUBCAPSULAR HEMATOMA: A RARE CAUSE OF SUDDEN UNEXPECTED DEATH

The spontaneous subcapsular hematoma of the liver is very rare. There are only a few reported cases in the literature. Most reported cases of liver hematoma often occur during pregnancy as part of the hemolysis, elevated liver enzymes, and low platelet count syndrome. The other causes may be due to amylosis, rupture of hepatocellular carcinoma, adenoma, focal nodular hyperplasia, hemorrhagic cyst, or hemopathy. Idiopathic spontaneous subscapular hematoma is a rare and often fatal condition.A a 43-year-old woman having Steinert disease died because of a fatal spontaneous liver hemorrhage occurring without any traumatism. Was not find any apparent cause that could explain this hemorrhage even after a histological study of the liver (Oualha Dorra, Aissaoui A., Belhaj Meriam, Mesrati, Mohamed A, Moussa Adnene, Salem N, Zakhama A, Chadly A. Am J Forensic Med & Pathol. 2017; 38 (1): 9–10).

FOCAL BREAST LESIONS-ASSESSMENT WITH DYNAMIC CONTRAST-ENHANCED MAGNETIC RESONANCE IMAGING (Abstract): **Aim:** To evaluate breast magnetic resonance imaging for the characterization of the breast lesions and compare to pathology. **Material and methods:** Our study included 64 subjects aged 21 to 76 years with newly discovered breast lesions by mammography and ultrasound who underwent contrast-enhanced MRI at Arcadia Medical Center, Iași between January and December 2016. The following were analyzed: lesion morphology (shape, contour and signal intensity), enhancement pattern and enhancement curve. **Results and discussion:** Of the total of 65 subjects 44 presented benign lesions and 20 malignant lesions. Lesion morphology was consistent with the pathological diagnosis in 59 cases (90.8%). The shape of the masses was mostly oval or round in the benign lesions (29 cases) and mostly irregular in the malignant ones (11 cases). The contour was lobular in 27 benign masses and irregular in 16 malignant lesions. Regarding signal intensity of the lesions we found that the cysts had a water signal intensity and the solid lesions various combinations of signals. **Conclusions:** The rapid upslope of the enhancement curve either the first 2 minutes is associated with malignancy and a plateau in the delayed phase with an uncertain diagnosis of malignancy. Benign lesions were round or oval, with well defined, smooth or lobulated margins, low signal intensity in T1 weighed images, high signal intensity in T2 weighted images, homogenous contrast uptake, persistent enhancement curve (fibroadenomas and fibrocystic changes) and no enhancement (cysts). Breast cancer is an irregular mass, with irregular or spiculated margins, variable signal intensity in T1 and T2 weighted images, heterogeneous contrast enhancement and washout enhancement curve.
Keywords: MASS LESIONS, MRI, ENHANCEMENT CURVE.

Among the breast lesions the most important is breast cancer, which constitutes a major medical, social and economic problem. Although reliable estimates are lacking in many countries, the incidence of breast cancer in Romania was 46.2 per 100,000 population in 2000 and was the main cause of death in women over 40 years old (28.2 per 100,000 population) (1, 2). The incidence of breast cancer increases with age, with two peaks at 45-50 and 55-65 years. Over 250,000 new cases of breast cancer are diagnosed every year in the European Union and 172,000 new cas-

es/year in USA (3, 4).

The symptoms related to the disease, its complications, the anxiety given by the diagnosis alone and the treatment have a great negative impact on quality of life. The long-term prognosis of breast cancer is worse than for other cancers; the 5-to 10-year mortality rate is approximately 35-50%. The cost of medical care is measured in billions of euro (5, 6).

Breast cancer is a complex disease with a variable combination of symptoms and signs. Many breast cancers occur in women without any identifiable risks; none of the risk factors is determinant and most of them have expression in women over 50 years of age (7, 8, 9). The early diagnosis of the tumor is highly important, because it reduces mortality and morbidity, increases the quality of life and makes possible a conservative surgical treatment (10, 11).

Dynamic contrast-enhanced (DCE) magnetic resonance imaging (MRI) of the breast is an important new tool for the detection and characterization of breast lesions. The use of DCE- MRI for breast cancer detection is based on the concept of tumor angiogenesis or neovascularity. Tumor-associated blood vessels have increased permeability, which leads to prompt uptake and release of gadolinium leading to a pattern of rapid enhancement and washout on MRI. This dynamic rapid enhancement pattern helps to distinguish breast cancers from benign lesions. Literature reports have shown that not all malignant lesions show enhancement at DCE-MRI with enhancement absent in up to 12-16% of known malignant lesions, mainly due to small tumor size and diffuse parenchymal enhancement. Diffusion-weighted imaging (DWI) sequences and apparent diffusion coefficient (ADC) can help the differential diagnosis between benign and malignant lesions; ADC is a quantifiable parameter of the molecular movement of water; studies depicted high ADC values in benign lesions and normal fibro-glandular breast tissue, and low values in malignant lesions (12).

MATERIAL AND METHODS

Our study included 64 female patients aged 21 to 76 years old, with newly discovered breast lesions by mammography and ultrasound who underwent contrast-enhanced MRI at the Iasi Arcadia Medical Center between January and December 2016. The following were analyzed: lesion morphology (shape, margins, signal intensity), enhancement pattern (homogenous, heterogeneous, thin or thick rim, dark or enhanced septations), enhancement curve (Kuhl curve): type III (washout) – malignant, type II (plateau) – undetermined and type I (progressive) – benign.

MRI examinations were performed using a Philips Achieva 1.5 T equipment; gadolinium contrast-enhanced breast MRI protocol included:

- patients were asked to sign the informed consent for MRI assessment and fill out a breast questionnaire;
- an intravenous line was placed; the patient was scanned in prone position, and each breast was centered within the aperture of the dedicated radiofrequency breast coil
- axial T1-weighted spin-echo sequences for localization;
- sagittal fat-suppressed T2 weighted sequences, with repetition time (RT) 4,600 ms and echo time (ET) 84 ms, field of view (FOV) 18 cm, matrix 256 x 192, contiguous 2-mm sections;
- 3D axial 3D fat suppression fast spin echo (FSE) 3D axial T1-weighted fast spin-

echo (FSE) fat-suppressed sequences before and every minute after gadolinium injection (0.1 to 0.2 mmol/kg, injection rate 2 mL/s), for 5 minutes, RT/ET 11.0/4.2, FOV 18 cm, matrix 256 x192, contiguous 2-mm sections;

RESULTS

Of the total of 65 subjects, breast MRI discovered in 44 (56.6%) cases benign lesions (fibroadenomas in 18 cases (27.6 %), fibrocystic changes in 14/21.5 %, cysts in 11/16.9%, and intra mammary lymph node in 1/1.5%) and malignant lesions in 21 (32.3 %).

The shape of the masses was mostly oval or round in the case of benign lesions (29 cases/65.9%) and mostly irregular in the malignant ones (11 cases/52.4 %). The contour was lobular in 27 (61.4%) benign masses and irregular in 16 (76.1%) malignant lesions.

We had studied also the signal intensity of the lesions: the cysts had water signal (low signal intensity in T1-weighted images and high signal intensity in T2-weighted images), but the solid lesions showed a heterogeneous signal, given by the components of the mass (solid, necrosis, mucin) and the most frequent was:

- isointense signal on T1- weighted and high signal intensity on T2- weighted images (16- 36.4%) in case of benign lesions;
- isointense signal on T1- and T2-weighted images and low signal intensity on T1-weighted and high signal intensity on T2-weighted images (6/ 28.5 % lesions respectively) in case of malignant lesions.

In our study the pattern of malignant tumors was as follows (fig. 1):

- irregular mass (11/52.4% cases), with spiculated or irregular margins (19/90.5%);
- the signal intensity was–low signal intensity on T1-weighted images and high signal intensity on T2-weighted images (6/ 28.5 % cases) and signal intensity on T1- and T2- weighted images like parenchyma (6-28.5% cases);
- heterogeneous contrast enhancement was the most frequent pattern (12/57.1%), followed by homogeneous (5/23.8%) and clumped enhancement (4/19%); thick rim, central enhancement, enhancing internal septations were not encountered;
- type III (washout) enhancement curve was demonstrated in most cases (12/ 7.4%)

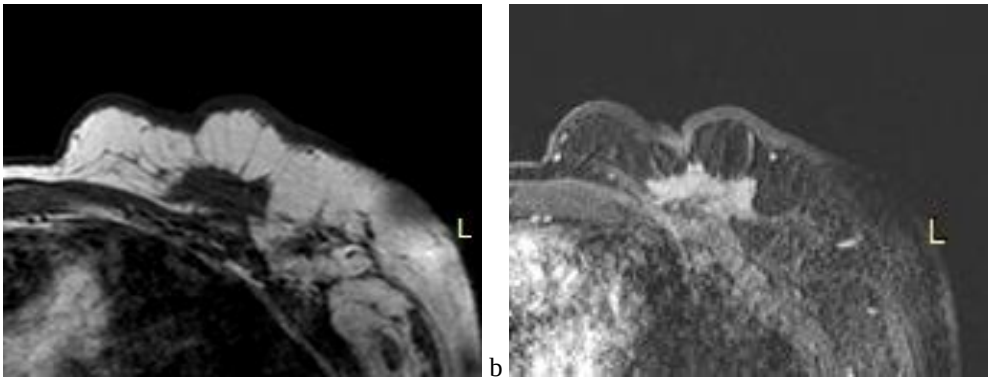

Fig. 1. Breast MRI, breast cancer with chest wall and nipple invasion - irregular mass, with spiculated margins, low signal intensity on T10 weighted images (a), homogeneous contrast enhancement (b)

• chest wall and nipple invasion or lymph node enlargement were additional features which confirmed the malignancy, but were found only in 4 cases with advanced disease.

Fibroadenomas were oval, with well-defined, smooth or lobulated margins, isointense on T1-weighted images, high signal intensity on T2-weighted images, homogeneous enhancement (17/ 94.4%) or dark (unenhanced) internal septations (1-5.5%), with a progressive enhancement curve (fig. 2).

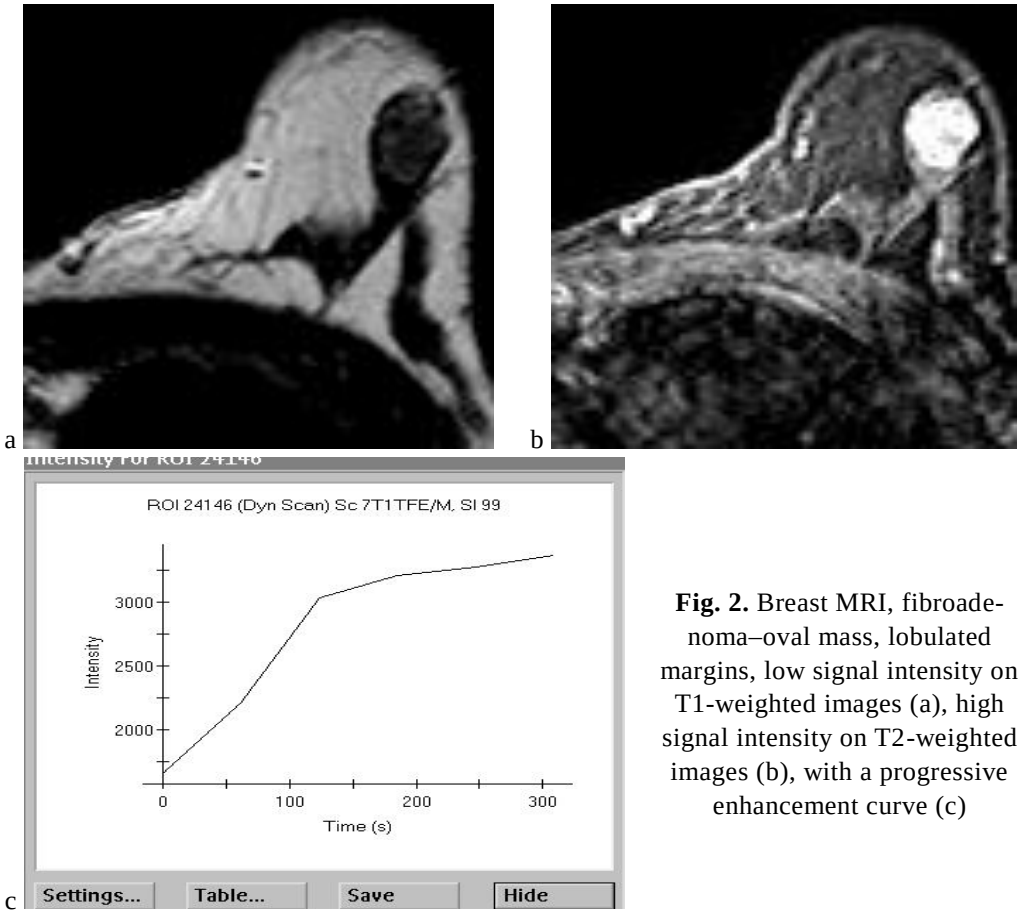

Fig. 2. Breast MRI, fibroadenoma–oval mass, lobulated margins, low signal intensity on T1-weighted images (a), high signal intensity on T2-weighted images (b), with a progressive enhancement curve (c)

All the cysts were oval or round, had smooth margins, maximum 35 mm in size, water signal intensity; 2 (18.2%) patients had cysts with thin-rim enhancement (inflammation around the cysts) and in 9 (81.8%) patients there was no contrast uptake.

At MRI, the fibrocystic parenchyma is difficult to distinguish from normal breast on non-

contrast-enhanced sequences; on post-contrast T1 weighted sequence stippled regional or heterogeneous contrast uptake was seen, which varies with the menstrual cycle. Enhancement curve had continuous (11/78.6%) or plateau (3/21.4%) pattern.

Single and clustered cysts of 3 mm to 23 mm in size, with no contrast enhancement were discovered, signal intensity being homogeneous in 12 (85.7%) cases (simple cysts) and heterogeneous, with fluid - fluid level in 2 (14.3%) cases (complicated cysts).

In one patient with ultrasound suspicion of breast nodule MRI detected an intramammary lymph node, which had an oval shape, smooth margins, central fat content and peripheral uptake of the contrast medium with progressive enhancement curve.

The morphology of the lesions was confirmed in 59 (90.8%) cases by the pathologic diagnosis.

DISCUSSION

In malignant tumors, we encountered various aspects:

- in our study the shape and margins of the lesions were like those reported in the literature: most of them had irregular shape, spiculated or irregular margins;
- signal intensity in our study was – low signal intensity on T1-weighted images and high signal intensity on T2-weighted images and signal intensity on T1- and T2-weighted images like parenchyma, compared to the data in the literature (signal intensity on T1-weighted image like that of parenchyma, and iso- to low signal intensity compared to parenchyma on T2-weighted image;
- heterogeneous contrast enhancement was the most frequent pattern, finding in agreement with the literature data, and thick rim or central enhancement, enhancing internal septations were not encountered;
- in agreement with the literature data, type III (washout) enhancement curve was demonstrated in most cases.

The pattern of most fibroadenoma cases in our study was like that described by preexisting studies: oval or round, with well-defined, smooth or lobulated margins, isointense on T1-weighted images, high signal intensity on T2-weighted images, homogeneous enhancement with a plateau enhancement curve.

Our study confirms that irregular shape is consistent with the diagnosis of malignancy (it was not encountered in any benign lesion). The oval or round shape was a pattern of benign lesion in 29 cases but was also found in 6 cases of malignant tumors; the oval or round shape had a relative risk (RR) of benign mass of 1.55 and an attributable risk (AR) of 0.59, so it is a pattern of benign lesions.

The irregular and spiculated margins were found only in the malignant tumors, but the lobular margins were encountered in 27 benign and 2 malignant masses; lobular margins had a RR of benign mass of 1.27 and an AR of 0.46, so it is a pattern of benign lesions.

Washout type of enhancement curve was found only in case of malignancy, but the progressive type was encountered in 25 benign and 7 malignant lesions, plateau type in 19 benign and 2 malignant cases. The progressive type of contrast uptake had a RR of benign mass of 1.27 and an AR of 0.21, so it is a pattern of benign lesions and the plateau type a RR=0.5 and AR = -21 so it is not consistent with a benign or malignant lesion (tab. I).

We found that the rapid upslope of the enhancement curve within the first 2 minutes is associated in 96% of cases with malignancy and a plateau in the delayed phase (minutes 2 to 5) can be associated with a 45% chance of benign and a 55% chance of malignant lesions.

TABLE I
MRI pattern of malignant and benign breast lesions

MRI pattern	Malignant lesion	Benign lesion
Shape	irregular	Round or oval
Margins	irregular or spiculated	Smooth or lobular
Enhancement	heterogeneous	homogeneous
Enhancement curve	washout	progressive
Signal intensity	isointense on T1, high signal on T2-weighted images	Variable signal intensity

CONCLUSIONS

The most notable finding of our study is that the rapid upslope of the enhancement curve within the first 2 minutes is associated with malignancy and while a plateau in the delayed phase is a cause of uncertain diagnosis of malignancy.

Benign lesions were round or oval, with well-defined, smooth or lobulated margins, low signal intensity on T1-weighed images, high signal intensity on T2-weighted images, homogeneous contrast, with a persistent enhancement curve (fibroadenomas and fibrocystic changes) and no enhancement (cysts).

Breast cancer is an irregular mass, with irregular or spiculated margins, variable signal intensity in T1- and T2-weighted images, heterogeneous contrast enhancement and washout enhancement curve.

CAN BIOELECTRICAL IMPEDANCE ANALYSIS HELP US IN MANAGING EASY AND FASTER OUR PATIENTS' HEALTH PROBLEMS? (Abstract) Bioelectrical impedance principle it is a new way of detecting abnormal cellular response. Wegamed devices use this method to discover in a holistic manner a view of the man in all dimensions, body, emotions and intellect, and correlate's the treatment with the characteristics of the individual at all these levels. The aim of the study was to see if using alternative medicine methods can we evaluate correct and noninvasive the patients. **Material and methods:** A retrospective study was conducted to investigate the correlations between the clinical and paraclinically diagnoses and the diagnoses offered by the Wegamed devices. The study includes 440 patients who referred to our clinic between January 2013 and January 2016, who were thoroughly examined through evidence-based medicine methods and then undergo the Test expert plus analyze. **Results:** This retrospective study showed a concordance for some pathologies and diagnostics. The concordance was 100% for acute or oncological pathologies and for other pathologies, mostly chronic, degenerative; the most important is the doctor, who must interpret and correlate, based on his/her experience. **Conclusion:** The classical diagnostic methods can provide accuracy, but a personalized treatment requires viewing the man in all dimensions and specific correlations with the characteristics of the individual. **Keywords**: ELECTRODIAGNOSTIC STUDY, HOLISTIC MEDICINE, WEGAMED DEVICES.

Bioelectrical impedance analysis (BIA) is based on the principle that electric current flows at different rates through the body depending upon its composition. The body is composed mostly of water with ions, through which an electric current can flow (1, 2, 3). The water in the body is localized in two compartments: extracellular water (ECW, approximately 45%) and intracellular water (ICW, approximately 55%) (4, 5, 6). On the other hand, the body also contains non-conducting materials (body fat) that provide resistance to the flow of electric current (7). Adipose tissue is significantly less conductive than muscle or bone (8, 9, 10, 11). The principal of BIA is that electric current passes through the body at a differential rate depending on body composition (3, 12). Hence, there is a direct relationship between the concentrations of ions and the electrical conductivity and an indirect relationship exists between the ion concentration and the resistance of the solution (6, 13, 14, 15).

Nowadays the scientists want to discover a perfect, cost efficient, fast and noninvasive method for a correct diagnose. A mixture between the principles of alternative medicine and the science based medicine may be the answer (16, 17).

For this study, we used 2 types of diagnostic devices from Wegamed based on the bioelectrical impedance characteristics (14). The first one, Text expert plus is a highly – sensitive skin-resistance measuring device designed for use on humans to register physical skin characteristics with respect to their normal, reactive and regulative magnitudes. Investigational and therapeutic options include:

- metabolic regulation testing & therapy program (using homeopathic test and therapeutic data);
- energy screening-automatic resistance measurement of predefined body segments;
- investigational and therapeutic application of pulse currents;
- in addition, by means of special electrodes, a current measurement cam be made to localize galvanic buccal currents.

The Test expert plus device makes causal indication investigations possible by means of holistic capture of the bioenergetics functional state of the human body, its organs and organ systems under normal conditions, as well as monitoring the course of diseases and therapies.

The second device, check medical sport, measures the whole-body. There are 6 electrodes attached to the patient's feet, hands and head. The electrodes are used to apply very low-intensity 13 Hz pulse currents to specific body regions. The current flowing between the two electrodes automatically seeks out the path of least resistance via the body's fluids. The condition and constitution of the tissue affects the system's resulting electrical conductance. For safety reasons, when using this device there are some exclusion criteria, such as: pregnancy, epilepsy, pacemakers, severe cardiac arrhythmia and general acute ailments (7, 14).

MATERIAL AND METHODS

A retrospective study was conducted to investigate the correlations between the clinical and paraclinically diagnoses and the diagnoses offered by the Wegamed devices.

The study includes 440 patients who referred to our clinic between January 2013 and January 2016, who were thoroughly examined through evidence-based medicine methods and then undergo the Test expert plus analyze. The cases consist of 37% men and 63% women, range, 14-97 years, with an average age of 57.8 years, all of them Caucasians.

Designed and developed as an electro acupuncture test device, it provides the prerequisite for bioelectronics regulatory diagnostics using the Wegatest method, including homeopathic remedy test. Known electromagnetic test signals are applied to an acupuncture point via the device's measurement circuit, which then lead to resonance phenomena with the organism and thus to resistance changes at the acupuncture point. In accordance with the applied test information, these resonance phenomena provide investigational information to the trained and qualified users.

The data obtained was processed with the purpose to investigate the relationship between the clinical diagnoses and the information offered by the Test expert plus analyze.

RESULTS AND DISCUSSION

The clinical diagnoses found are divided in 32 main pathology groups. In this article

are reviewed the first 4 major diseases found in the selected group: common lombosciatic syndrome, spondyloarthropathy, knee osteoarthritis and one major group that contains all cardiovascular pathologies.

Test expert plus analysis showed that the main organs with abnormal electrical response are the head (more than 50% of the patients), the large intestine and the lumbar area (fig. 1).

TABLE I.

Clinical diagnosis.

Clinical diagnosis	No. %
Common lombosciatic syndrome	30.00%
Spondyloarthropathy	18.86%
Knee osteoarthrosis	16.14%
Cardiovascular pathology	11.14%
Arthralgia	10.00%
Osteoarthrosis	9.77%
Cervicobrachial neuralgia	9.77%
Herniated disc	7.95%
Gastroenterological pathology	7.05%
Chronic lumbago	6.82%
Neurological pathology	6.36%
Coxarthrosis	5.68%
Osteoporosis	5.23%
Periarthritis scapula humeralis	4.09%
Endocrinological pathology	3.41%
Trauma	3.18%

TABLE II

Clinical diagnosis.

Clinical diagnosis	No. %
Discopathy	2.95%
Otolaryngology pathology	2.27%
Arnold / Luschka neuralgic	1.82%
Temporomandibular arthrosis	1.82%
Calcaneal spur	1.82%
Cervical arthropathy	1.59%
Vertebrobasilar insufficiency	1.14%
Tendinitis	0.91%
Rheumatoid arthritis	0.91%
Ankylosing spondylitis	0.68%
Anemic syndrome	0.68%
Algoneurodystrophy	0.45%
Pulmonary pathology	0.45%
Lumbar spinal stenosis	0.23%
Gout	0.23%
Brahial plexus injury	0.23%

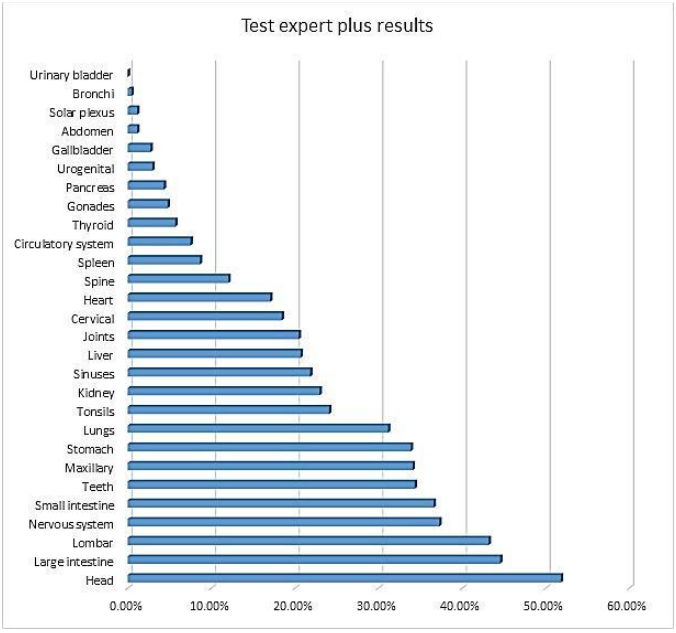

Fig. 1. Test expert plus results.

A. **Common lombosciatic syndrome**. In the selected group were diagnosed 132 (30%) patients with common lombosciatic syndrome. 73 (55%) were women and 59 (45%) men. These patients also presented other pathologies represented in figure 3. 27 (20.45%) cases suffered from spondyloarthropathy, 25 (18.9%) patients were diagnosed also with knee osteoarthritis and 18 cases (13.63%) had herniated disc problems. At the evaluation of the entire body with the Test expert plus, 67 (50.75%) patients had the lumbar region affected. The next organ that presented modifications was the large intestine, found abnormal in 62 (46.96%) cases.

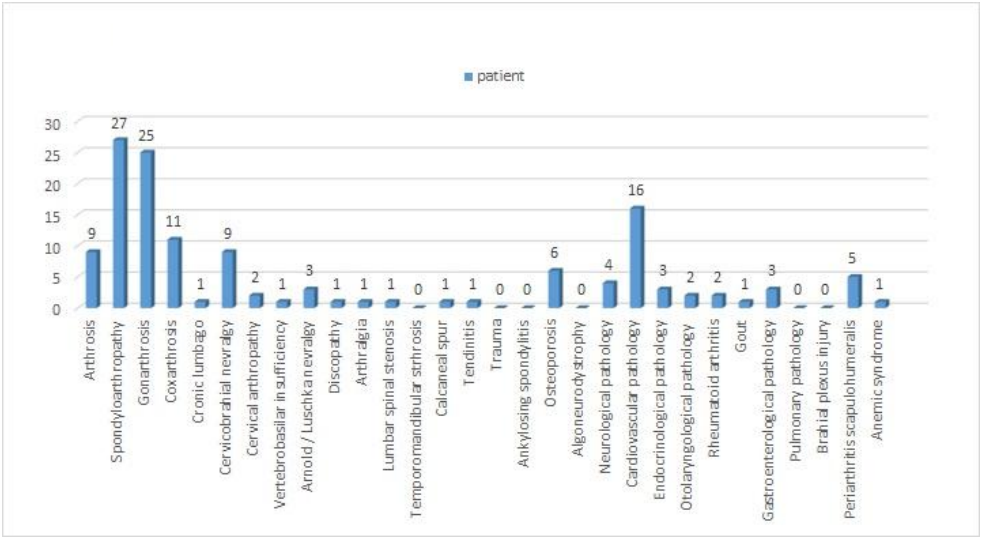

Fig. 2. Clinical diagnosis of the patients with common lombosciatic syndrome.

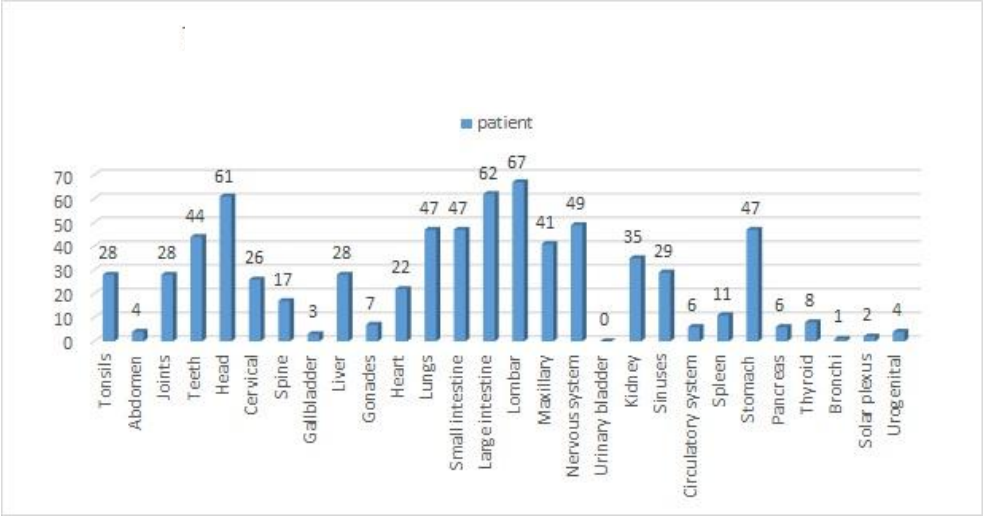

Fig. 3. Test expert plus results from patients with common lombosciatic syndrome.

B. **Spondyloarthropathy**. There were diagnosed clinical and paraclinically 83 (18.86%) patients with spondyloarthropathy. In 27 (32.53%) cases, this disease was associated with common lombosciatic syndrome and with knee osteoarthritis in 17 (20.48%) cases (fig.4).

C. The results from Test expert plus analyze showed that 47 (56.6%) patients presented alteration of the electrical signal in the region of the head. The large intestine was affected in 42 (50.6%) cases. The number of the patients with digestive problems at any level exceeds the number of the patients with spondyloarthropathy, therefore is a strong correlation of the spondyloarthropathy and digestive system alteration (fig. 5).

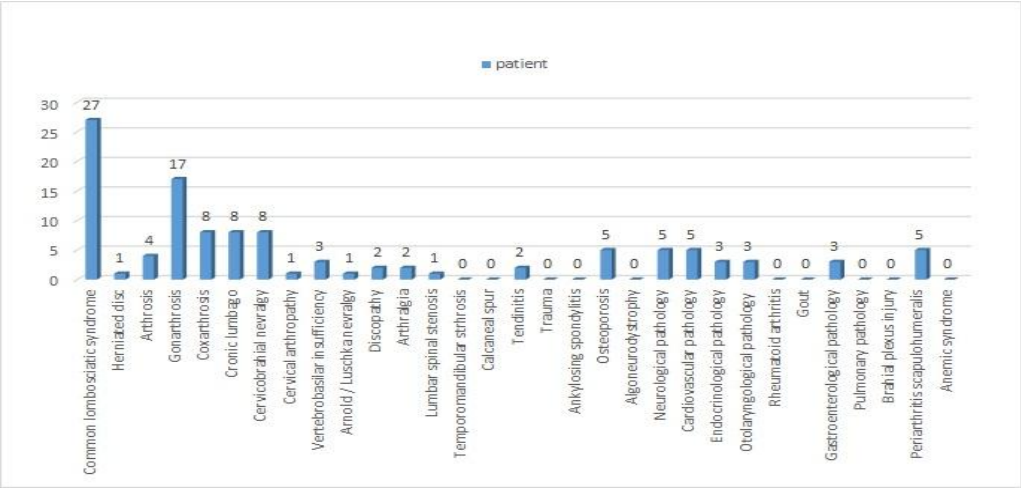

Fig. 4. Clinical diagnosis of patients with spondyloarthropathy.

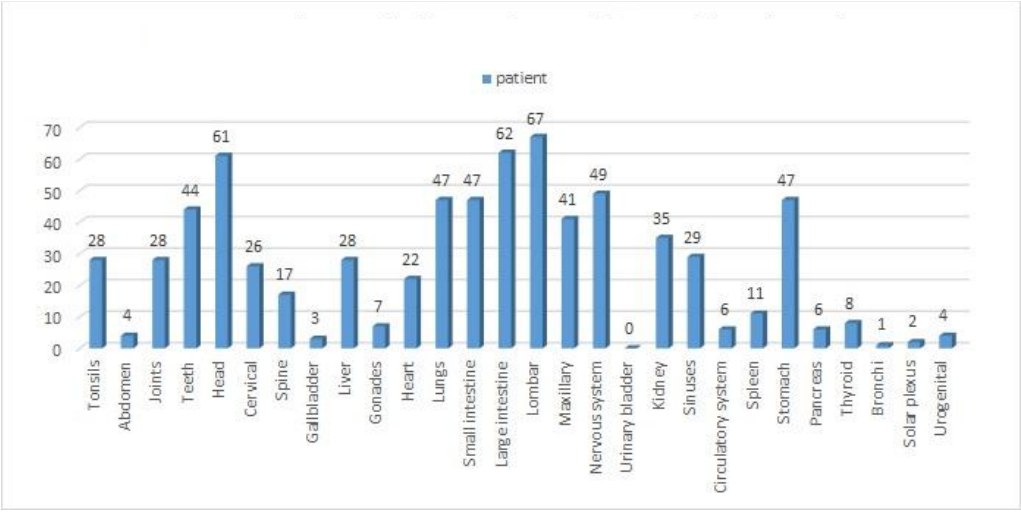

Fig. 5. Test expert plus results from patients with spondyloarthropathy.

D. **Knee osteoarthritis**. From the selected group, 71 (16.14%) patients were diagnosed with knee osteoarthritis. 24% of those patients had older degenerative osteoarticular pathologies. 14 (19.71%) cases had associated cardiovascular diseases (fig. 6).

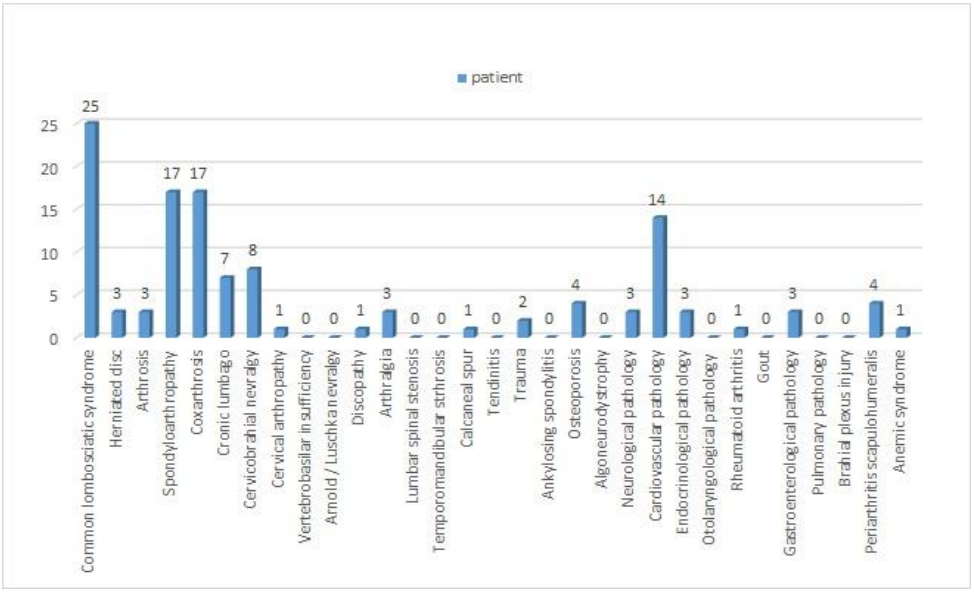

Fig. 6. Clinical diagnosis of patients with spondyloarthropathy.

Test expert plus evaluation results are similar with the ones mentioned above. Thus, 38 (53.3%) of patients presented large intestine modifications. The head region had the electrical signal altered in 35 (49.2%) cases. For this disorder, also exists a strong correlation with one or more digestive system problems (fig. 7).

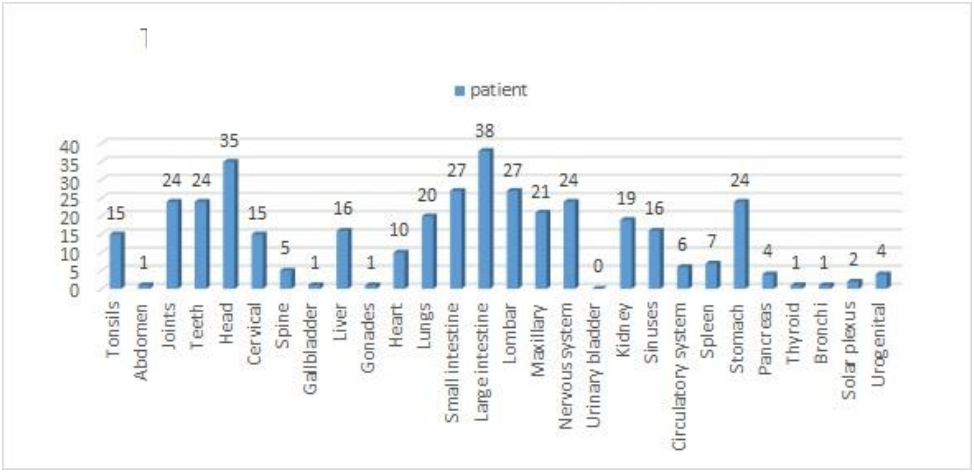

Fig. 7. Test expert plus results from patients with knee osteoarthritis.

E. **Cardiovascular pathologies**. 45 (11.14%) cases were initially diagnosed with cardiovascular pathologies. 16 (33.5%) associated common lombosciatic syndrome and 14 (31.1%) suffered from knee osteoarthritis (fig. 8). Test expert plus investigation showed that 24 (53.3%) of patients presented modifications of the electrical response at the head level and 22 (49%) of cases at the nervous system level (fig. 9).

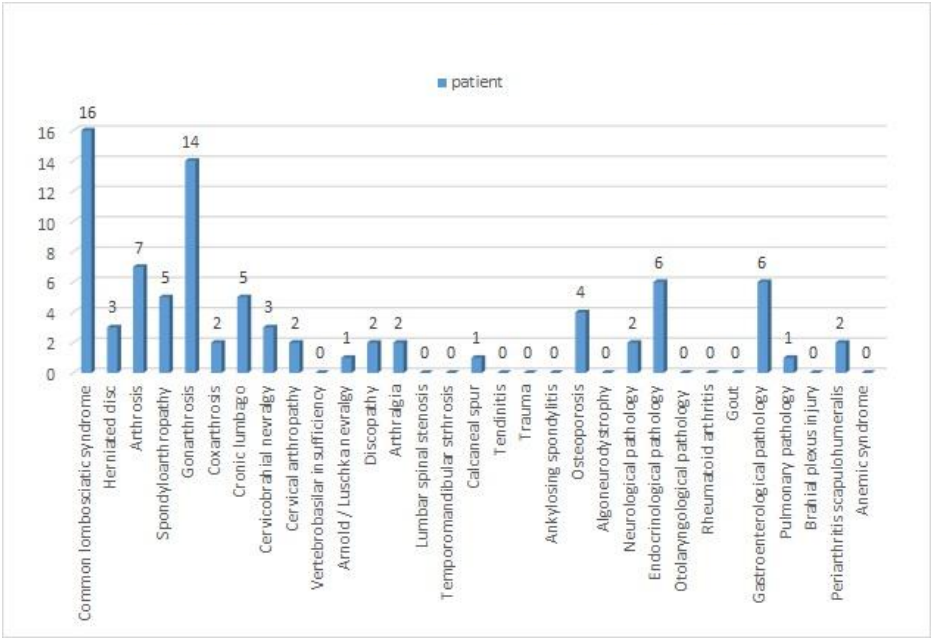

Fig. 8. Clinical diagnosis of patients with cardiovascular pathology.

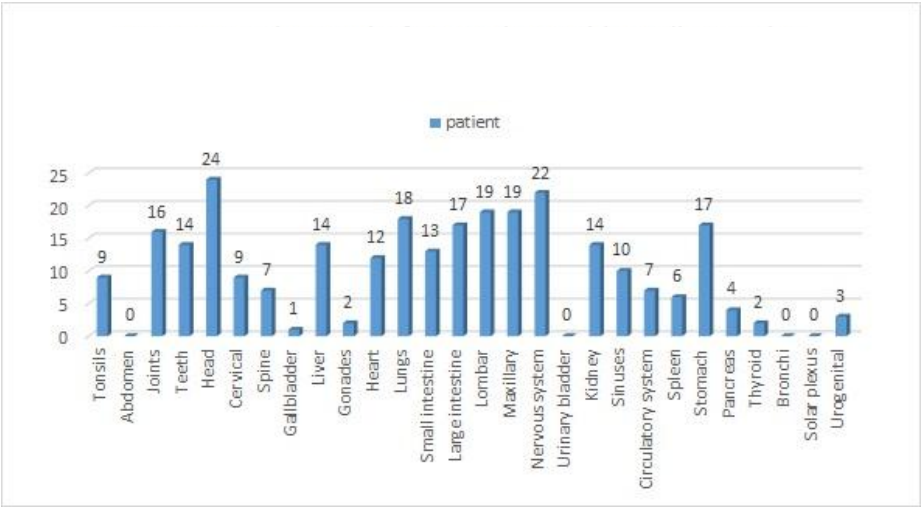

Fig. 9. Test expert plus results from patients with cardiovascular pathology.

Next, we will illustrate 2 cases that reveal the benefits and the limitation of this holistic method of diagnose.

Case study 1: female patient, 60-years-old, with family history of colon cancer, presented for cervical spondylosis. The Wegamed electro diagnostic revealed an important energetic anomaly concerning the inferior digestive system. Clinical and paraclinically diagnostic did not show any pathological signs at that level and based on the Wegamed study, we recommended a colonoscopy with biopsy, which revealed numerous polyps in the large intestine in a pre-malignant stage (fig. 11).

Case study 2: male patient 60-years-old, diagnosed with ankylosing spondylitis stage IV. The patient has a good functionality overall but his physical impairments affect his daily living activities. The Wega test showed moderate to severe impairment in all major organs affected by the disease. Also, there were low energy resources.

The dental examination showed minimal-moderate inflammation (fig. 12).

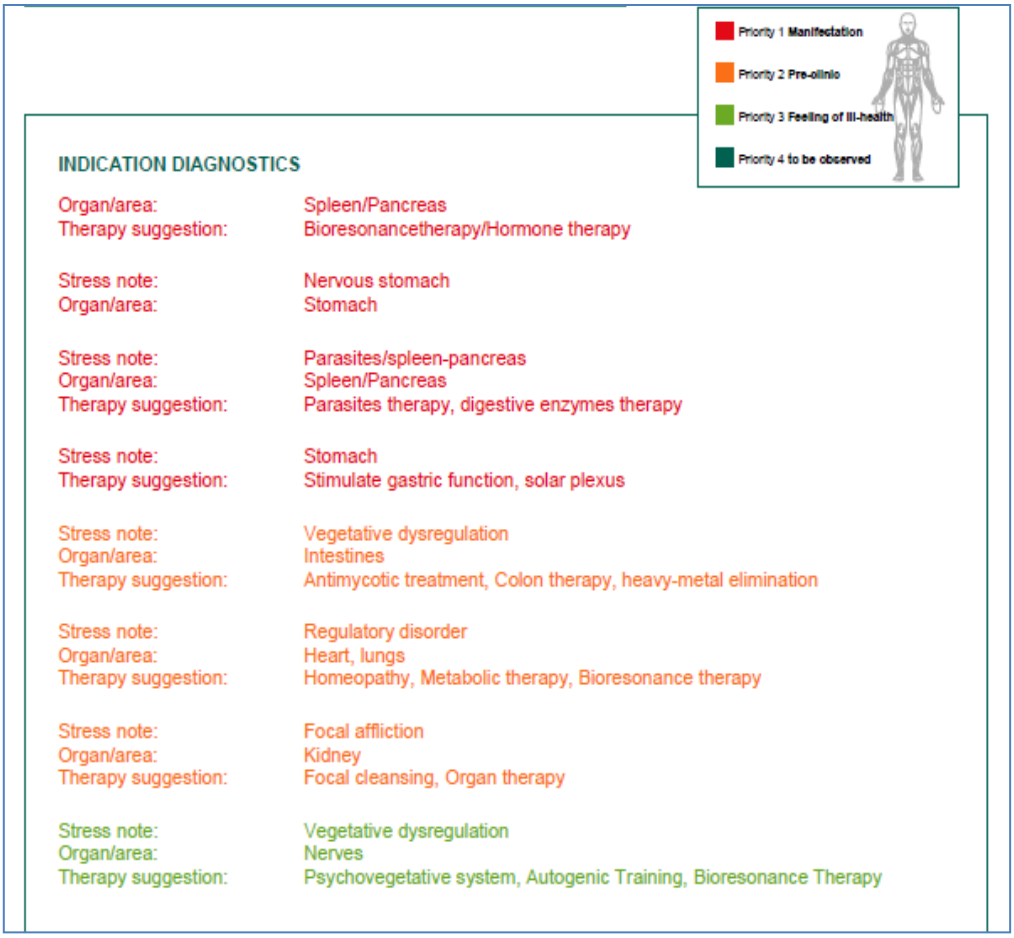

Fig. 10. Wegamed analyze of case study 1 revealing the inferior digestive system.

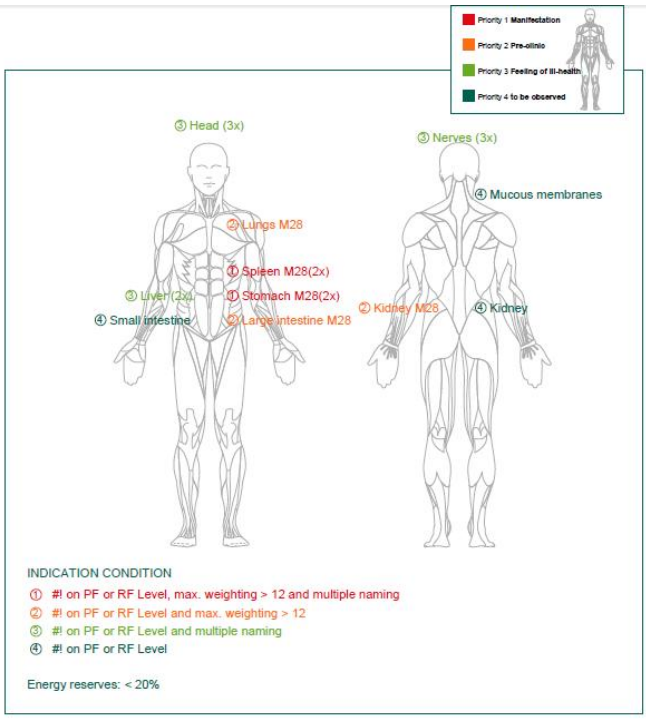

Fig. 11. Wegamed analyze of case study 2 showing moderate to severe impairment in all major organs affected by the disease.

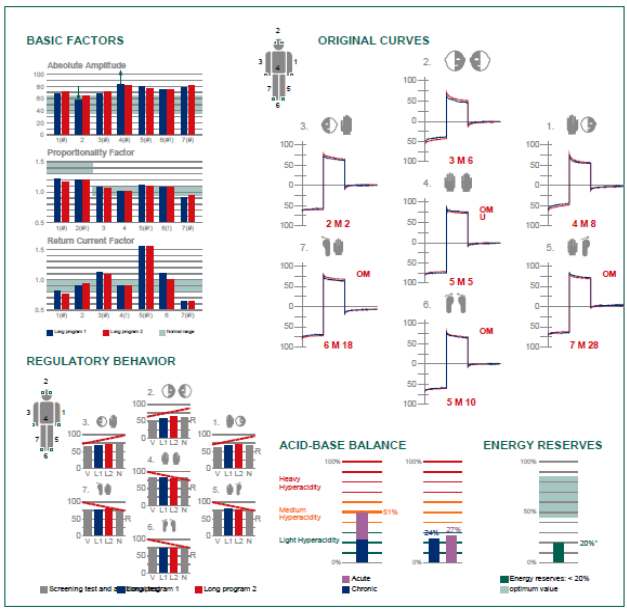

Fig. 12. Wegamed analyze of case study 2 that reveals low energy resources.

CONCLUSIONS

In our research the statistical analysis based on the correlation between primary and secondary diagnostics of the cases and Wegamed devices analyze was done to find a concordance between these two methods of diagnostic. This showed that for some pathologies and diagnostics the concordance is 100% and for other pathologies, mostly chronic, degenerative, the most important is the doctor, that must correlate based on his/her experience.

Based on the obtained results we should view in our medical practice the patient in all dimensions, body, emotions and intellect, and to correlate the treatment with the characteristics of the individual at all these levels.

The classical diagnostic methods provide accuracy to the molecular level, but it doesn't correlate in functionality over time. Bioelectrical impedance analysis (BIA) could be cost efficient, fast and noninvasive method associated with the classical diagnosis methods.

Further studies are needed to understand the intimate correlation mechanism between classical diagnostic and bioelectrical impedance analysis (BIA).

ACKNOWLEDGMENTS

The study was performed with the help from Wegamed GMBH (Am Zehnthof 189 D-45307 Essen, Germany). The work would not have been possible without the help and support from Dr. Peter Moloney (CEO GMBH).

HYPERTHERMIC INTRAPERITONEAL CHEMOTHERAPY – A CUTTING EDGE THERAPHY FOR ADVANCED OVARIAN CANCER?

Nowadays, it is well known the importance of hypertermic intraperitoneal chemotherapy in colo-rectal cancer, pseudomyxoma peritoneii and malign mesothelioma, but it's significance in advanced ovarian cancer isn't so certain so far. There were published the results of a phase II study performed at the Unit of General, Emergency and Transplant Surgery at Sant'Orsola-Malpighi Hospital, University of Bologna, Italy, the Unit of General Surgery and Gynaecologic Surgery of Papa Giovanni XXIII Hospital, Bergamo and the Unit of Gynaecology of the Jena University Hospital, Germany. Patients with primary, advanced (FIGO stage IIIC to IV), or recurrent EOC were eligible for the present study to be treated with cytoreductive surgery and HIPEC with Cisplatin (100 mg/m^2) and Paclitaxel (175 mg/m^2). It seems that using cytoreductive surgery and HIPEC, using cisplatin and paclitxel it is feasible and comparable with the other drugs regimens with similar mortality and morbidity rate. The benefit for the overall survival and for the morbidity and mortality rate, it seems that it's a statement for the treatment in ovarian cancer (Federico Coccolini, Luca Campanati, Fausto Catena et al. Hyperthermic intraperitoneal chemotherapy with cisplatin and paclitaxel in advanced ovarian cancer: a multicenter prospective observational study. *J Gynecol Oncol*. 2016 Jan;26(1):54-61).

INFLAMMATORY AND GENETIC MARKERS (APO B100 AND ANGIOTENSIN-CONVERTING ENZYME GENE) IN THE CORONARY ARTERY DISEASE (Abstract) **Aim**: To analyze the correlations between inflammation markers and ApoB100 and angiotensin converting enzyme (ACE) gene polymorphism and the severity of coronary artery disease (CAD). **Material and Methods**: We conducted a study in 58 patients with acute coronary syndromes (ACS) who underwent coronarography at the Iasi 'Prof. Dr. George I. M. Georgescu' Institute of Cardiovascular Diseases. The patients included in the studies were selected from those who needed a coronarography for unstable angina or acute myocardial infarction. The data were uploaded and processed using the statistical functions in SPPS 18.0 at a 95% materiality threshold. **Results**: Elevated inflammation markers were found in all study patients, with small differences in distribution. None of the study patients presented ApoB100 gene mutations. As to ACE polymorphism, a predominance of genotype II in unicoronary patients and ID and DD genotypes in bicoronary and tricoronary patients was found. **Conclusions**: The results of our study confirm the role of genetic and epigenetic factors in the severity and progression of the coronary disease, leaving room for larger and more comprehensive studies and new research perspectives. **Keywords**: CORONARY ARTERY DISEASE, APOB100, ANGIOTENSIN CONVERTING GENE, STENOSIS, ACUTE CORONARY SYNDROME

Acute coronary syndromes (ACS) are the most common cause for hospitalization among patients with coronary artery disease (CAD). The term acute coronary syndrome refers to a large spectrum of diseases including unstable angina (UA), acute myocardial infarction without ST segment elevation (NSTEMI) and acute myocardial infarction with ST segment elevation (STEMI) (1). More than 90% of the cases are caused by coronary atherosclerosis. The pathophysiological mechanism consists of an interaction between plaque rupture, platelet activation and thrombus formation, endothelial dysfunction, spasm, vascular remodeling (2). Risk factors for CAD were officially de-

scribed based on the discoveries of the Framingham study: age, smoking, high total cholesterol level, hypertension, obesity, diabetes, metabolic syndrome, C reactive protein, homocysteine. The latest discovery is represented by genetic factors: polymorphisms in the angiotensin converting enzyme (ACE) gene and ApoB100 gene (3).

ACE gene is located on the chromosome 17q23. It has 21 kb and comprises 26 exons and 25 introns (4). The gene polymorphism is due to the insertion (I) or deletion (D) of an alu sequence in intron 16 that leads to the generation of three genotypes: insertion/insertion (II), deletion/deletion (DD) or insertion/deletion I/D) (5, 6). I/D polymorphism is associated with the circulating and tissue ACE levels. Homozygotes DD have a higher level compared to the homozygotes II or heterozygotes (7). ACE polymorphisms explain many of the physiological variations of the cardiovascular system (8). Therefore, these genetic differences have been associated with many diseases such as arteriosclerosis (9), arterial hypertension (10) and CAD. In its genetic variants, ACE may be associated with the cardiovascular risk factors in predicting CAD development and severity (11,12).

The human ApoB100 is located on the short arm of the chromosome 2 (13) and it encodes the main apolipoprotein of chylomicrons and LDL-cholesterol, the mutations contributing to the occurrence of dyslipidemia, risk factor of the coronary disease (14). The polymorphism is multiple. One of the mutations is the substitution of adenine with guanine at the level of codon 3500 Apo B100 (15).

MATERIAL AND METHODS

We conducted a study in 58 patients with ACS who underwent a coronarography at the Iaşi 'Prof. Dr. George I. M. Georgescu' Institute of Cardiovascular Diseases. The patients were divided into two subgroups depending on the type of disease: AMI subgroup (30 patients with acute myocardial infarction) and UA (18 patients with unstable angina).

The experimental protocol was approved by the Ethics Committee, the procedures being consistent with the Declaration of Helsinki II, and all patients signed an informed consent before enrollment into the study.

A thorough physical examination was done and a detailed personal and family history was obtained. The severity of coronary disease was assessed according to the number of diseased coronary arteries with above 70% stenosis (no, one, two, or three coronary arteries = 0, 1, 2, 3 C).

Also evaluated was the presence of conventional risk factors (1. hyperlipidemia, 2. hypertension, 3. diabetes, 4. family history of ACD, 5. smoking, 6. obesity), their analysis being performed according to well-defined criteria.

For gene dosage analysis, 200 ml peripheral venous blood EDTA samples were collected from each patient, and DNA was automatically extracted. After checking DNA purity, we performed the gene amplification by the polymerase chain reaction (PCR). The result was the determination of polymorphism in the ACE (DD, ID, II) and apoB100 genes (pro/pro, pro/pat, pat/pat).

The data were uploaded and processed using the statistical functions in SPPS 18.0 at the materiality threshold of 95%.

RESULTS

Erythrocyte sedimentation rate (ESR) ranged from 2 to 130 mm/h (fig. 1) in 62.1% of the patients, the individual values

exceeding the upper limit of reference range (<20 mm/h). Depending on the coronary disease, a slightly higher average ESR value was found in the subgroup with unstable angina (31.63 *vs* 35.07 mm/h; p=0,660).

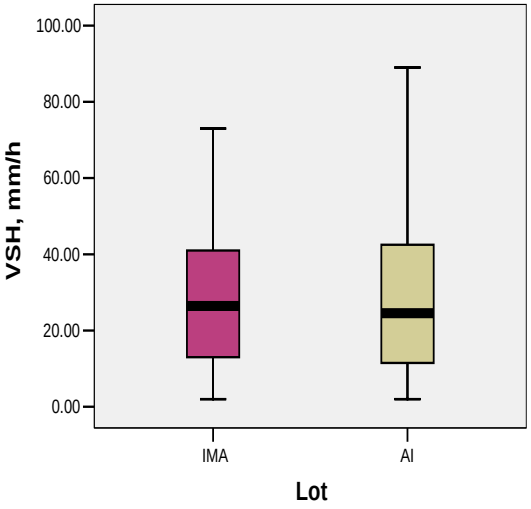

Fig. 1. Mean ESR values

The individual *C reactive protein (CRP)* levels were in the range 0.30-77 mg/dl, 53.4% of the values being above the reference range (<4 mg/dl). The average CPR level in the AMI group was slightly higher than in the UA group, but without significant differences (8.61 *vs* 7.57 mg/dl; p=0.715) (tab. I).

TABLE I

Descriptive indicators of CRP (mg/dl) depending on the epidemiological characteristics

Subgroup	N	Average	SD	SE	Confidence interval 95%		Min	Max	Test F (ANOVA) p
					-95% CI	+95% CI			
AMI	30	8.61	13.85	2.53	3.44	13.78	0.30	77.00	0.715
UA	28	7.57	5.69	1.08	5.37	9.78	1.10	25.00	
Total	***58***	***8.11***	***10.64***	***1.40***	***5.31***	***10.91***	***0.30***	***77.00***	

SD = standard deviation; SE= standard error

Fibrinogen The individual values of this parameter varied in the range 276-1012 mg/dl, 51,7% being over the reference limit (<500 mg/dl) (fig. 2). The average values of fibrinogen did not register significant differences depending on the coronary disease (554 *vs* 545 mg/dl; p=0,845) (tab. II).

In this study, most patients (41.4%), had significant (over 75%) stenosis of one coronary artery (1 CA) but together patients with 2 or 3 over 75% stenosis coronary arteries accounted for 57% of the patients (fig. 3).

TABLE II

Descriptive indicators of fibrinogen (mg/dl) depending on the epidemiological characteristics

Subgroup	N	Average	SD	SE	Confidence interval 95%		Min	Max	Test F (ANOVA) p
					-95% CI	+95% CI			
AMI	30	554.00	143.39	26.18	500.46	607.54	374	959	0.845
UA	28	545.00	202.96	38.36	466.30	623.70	276	1012	
Total	58	549.66	173.19	22.74	504.12	595.19	276	1012	

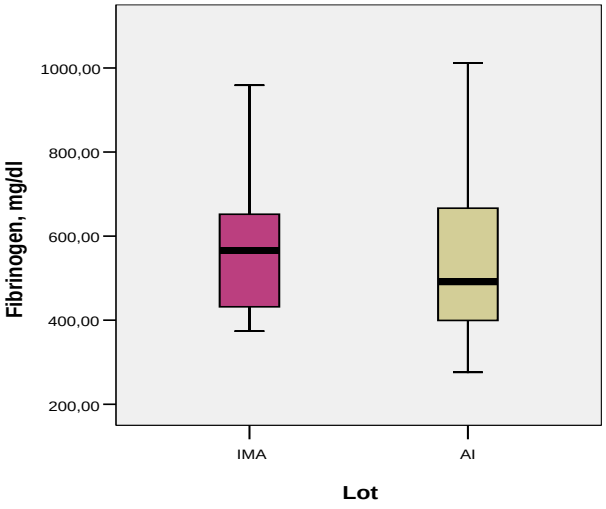

Fig. 2. Mean fibrinogen values

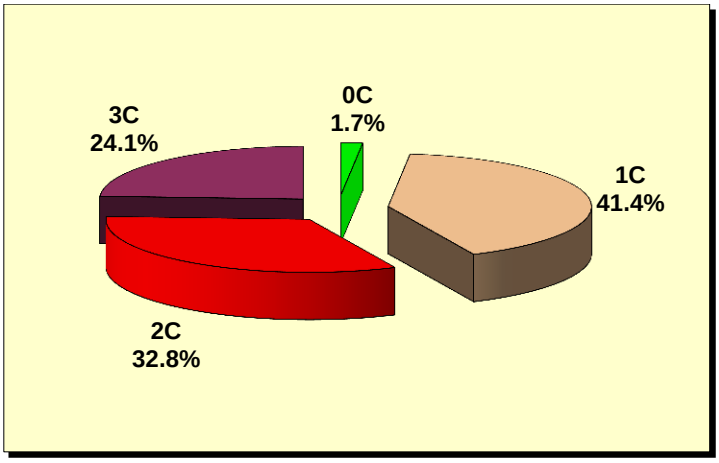

Fig. 3. Distribution of cases according to coronary status

Regarding the genetic polymorphism, no mutations in ApoB100 gene were identified.

Only normal fragments were noticed, healthy homozygote 140 bp (base pairs), without 140/110 bp (mutant heterozygote) or 110 bp (mutant homozygote) (fig. 4).

Regarding the ACE gene, all three genotypes (II, ID, DD) were identified: 3 II, 5 DD and 11 ID.

There are noticed the characters of homozygote II (480 bp), heterozygote ID (480/190 bp) and homozygote DD (190 bp) (fig. 5).

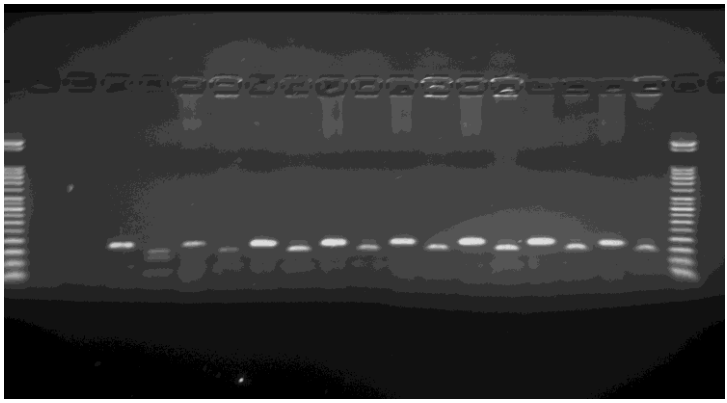

Fig. 4. ApoB100- detection of amplified and digested DNA

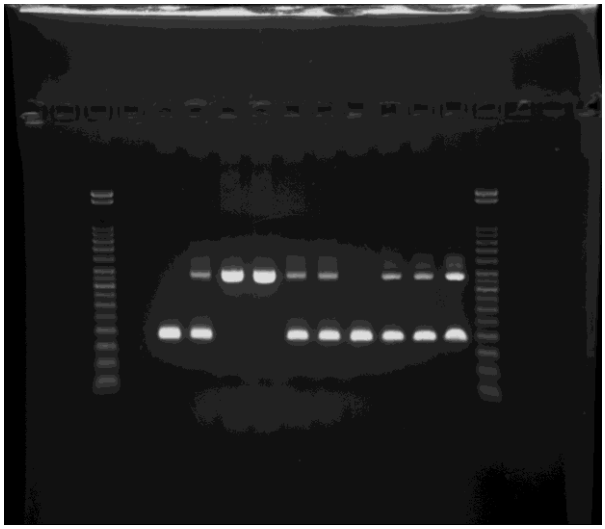

Fig. 5. ACE gene-detection of amplified and digested DNA

DISCUSSION

Similar to the literature (16, 17), inflammation was present in all enrolled patients, with small differences in the distribution of inflammatory markers in the two subgroups: ESR slightly increased in the UA subgroup, CRP slightly increased in the AMI subgroup, while the mean fibrinogen

levels did not show significant differences depending on the coronary artery disease.

In our study we did not identify patients with mutations of ApoB100 gene. Therefore, in our study subgroups, the ApoB100 gene polymorphism is not a risk factor.

As to the ACE polymorphism, there was a predominance of genotype II in unicoronary patients and of ID and DD in the bicoronary and tricoronary ones.

Our results are consisted with other studies in the literature. For example, Dhar et al. (16) studied 217 cases diagnosed with CAD and 255 healthy, age-and sex-matched controls with negative stress test. There were performed medical tests, such as electrocardiography, echocardiography, stress test, in addition to the laboratory analysis across all studies and mentioned at the beginning of the analysis. The results showed that both DD [OR: 2.16; 95%CI: (60.60e67.40)] and ID [OR: 1.48; 95%CI: (93.28e97.72)] genotypes of the ACE gene had a significant influence on the development of CAD. Coexistence of diabetes and hypertension proved to be risk moderating. Tobacco use increased the risk of disease in those with predisposing genotypes. DD and ID genotypes proved to be predisposing factors for CAD cases in their study population.

Other studies were negative. Poorgholi et al. (17) conducted a crossover study of 1950 patients referred for coronary angiography. They determined the genotype ACE in 767 CAD-positive patients (documented angiographycally and by Gensini score over 6) and 374 patients without CAD. The results showed that 504 patients (74.6%) in the group CAD positive were men, and the average age of this group was 60 (60 ± 10). In the group without CAD, the average age was 56 (56 ± 10) and 196 of them were men (52.4%). The analysis of groups and subgroups by gender did not objectivized significant differenced regarding the genotypes (p for the frequency of genotypes and allele being 0.494 and 0.397). Therefore, the genetic polymorphism of ACE was not associated with the severity of the coronary disease in the population of Iran.

However, other studies do not support this association. Thus, Poorgholi et al. (17) conducted a crossover study of 1050 patients referred for coronary angiography. ACE gene I/D polymorphism was determined in 676 CAD-positive patients (documented angiographically and by Gensini score over 6) and 374 CAD-negative patients. The results showed that 504 (74.6%) of the CAD-positive patients were men, and the mean age of this group was 60 (60 ± 10). In the CAD-negative group the mean age was 56 (56 ± 10) and 196 of them were men (52.4%). The analysis of groups and gender subgroups did not show significant differences (p values for genotype and allele frequency being 0.494 and 0.397, respectively). Therefore, ACE gene I/D polymorphism was not associated with the severity of CAD in the population of Iran.

CONCLUSIONS

The results of our study confirm the role of the genetic and epigenetic factors in the severity and progression of the coronary artery disease, leaving room to larger and more comprehensive studies and new research perspectives.

MEDICAL PRACTICE IN CHILDREN PRESENTING FEVER WITH PETECHIAL RASH TO AN EMERGENCY DEPARTMENT (Abstract) **Introduction:** The association of fever and petechiae in children is one of the most alarming findings for a paediatrician. To quickly distinguish between benign and life-threatening conditions is challenging in many cases. We aimed to evaluate the clinical practice of children presenting with fever and petechiae as initial symptoms. **Methods:** 41 patients (age 3 months-11 years) presenting with fever and petechiae were identified in an Emergency Paediatric Assessment Unit over a period of 9 months. General data, symptoms and signs were assessed for each patient. The work-up consisted in: complete blood count, inflammatory tests, coagulation tests, Monospot test, nasopharyngeal rapid tests, blood culture, and cerebrospinal fluid culture where appropriate. **Results:** Most children were <5 years of age (70.7%). Female to male ratio was 1:2.4. The most common clinical diagnoses were: viral respiratory illness (48.8%, 20/41) and upper respiratory tract infection (17.1%, 7/41). Meningococcal disease was found in one case. CRP>6 mg/l was poorly correlated with serious illness. The following variables were strongly associated with serious illness: ill appearance, shivering, lethargy, back rigidity, ESR>50 mm/h and prolonged capillary refill time. 59%(24/41) of children were treated with antibiotics, however, at discharge 42%(10/24) of them, did not have a work-up suggestive for a bacterial illness. **Conclusions:** Screening for low prevalence but high morbidity conditions, as the meningococcal disease, with an extensive work-up is time and resource consuming and may lead to unmotivated antibiotic use. Larger studies are needed to change the emergency practice for management of fever and rash. **Keywords:** FEVER, RASH, MENINGOCOCCAL DISEASE, CHILDREN.

The evaluation of febrile children presenting with petechial rash poses major management predicaments, especially in the emergency department and has been a topic of much debate(1–5). . Back in 1989, Baker at all published a study involving 190 patients admitted for fever and petechial rash and concluded "no laboratory test or physical finding was sufficiently sensitive to detect all patients with serious

disease". In 2000, Brogan and Raffles (6) proposed the "ILL" criteria. Irritability, lethargy, prolonged capillary refill and white blood count (WBC) outside the range 5–15 × 10^9/l, and C-reactive protein (CRP) greater than 5 mg/l, were considered risk factors for detection of serious illness. The authors proposed that children with fever and petechial rash who have none of the "ILL" criteria and normal WBC and CRP, to be observed for 4 hours and reassessed. If no deterioration occurred, then outpatient care would be recommended. Children who were not "ILL" but had abnormal WBC and/or CRP could be treated for meningococcal disease with a minimum of 48 hours antibiotics pending blood cultures, with notification of "suspected" meningococcal disease. The children, who presented one or more of the proposed criteria, plus abnormality of the WBC and/or CRP, would be treated as meningococcal sepsis, with consideration of early intensive care referral.(6)

Emergency department physicians, when faced with a child presenting with petechial rash and fever need to rule out meningococcemia or other causes of bacterial sepsis and often request extensive work-ups, (including blood cultures, cerebrospinal fluid (CSF) analysis), recommend antibiotics and hospital admission (5,7,8). Serious bacterial infections are the cause of substantial mortality and morbidity in children and paediatricians need to identify these children so appropriate treatment can be initiated (9–11). However, the efficiency of this approach needs to be optimized in order to avoid unnecessary investigations and treatments.

We aimed to evaluate the medical practice, in children presenting with fever and petechial rash in an emergency paediatric assessment unit.

MATERIAL AND METHODS:

Study group and data collection:

Consecutive children presenting to the Emergency Department with fever and petechial rash as initial symptoms between August 2011 and April 2012 were eligible for the study. The Hospital is a Regional Hospital in the midlands of Ireland.

The study involved 44 patients (age 3 months- 11 years) presenting with fever and rash as initial symptoms. Three children were excluded from the analysis as they presented 10-15 petechiae above the nipple line considered a result of coughing/vomiting. They had no blood work done, were followed for 4 hours and discharged.

The following variables were assessed by the treating physician: general data (referral, age in years, onset in days, treatment before presentation, treatment during and after admission); Symptoms and signs (General: ill appearance, refusing food, headache, shivering, capillary refill time, hypotension, tachycardia, cold limbs; Neurologic: irritability (inconsolable crying or screaming), lethargy, altered mental state, bulging fontanel, photophobia, positive Kerning sign, positive Brudzinski sign, abnormal pupil, seizures, unconsciousness, paresis; Gastroenterological: vomiting, abdominal pain, diarrhoea; Musculoskeletal: muscle pain; Respiratory symptoms and signs; Ear nose throat symptoms). The work-up consisting in: complete blood count, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), polymerase chain reaction assay (PCR), prothrombin time (PT), activated partial thromboplastin time, Monospot test, nasopharyngeal rapid tests and blood culture. Cerebrospinal fluid (CSF) culture where performed in 6 children with the clinical suspicion of meningitis.

The protocol used to guide the management of a child presenting fever and petechial rash presenting in our Emergency Department is presented in fig. 1.

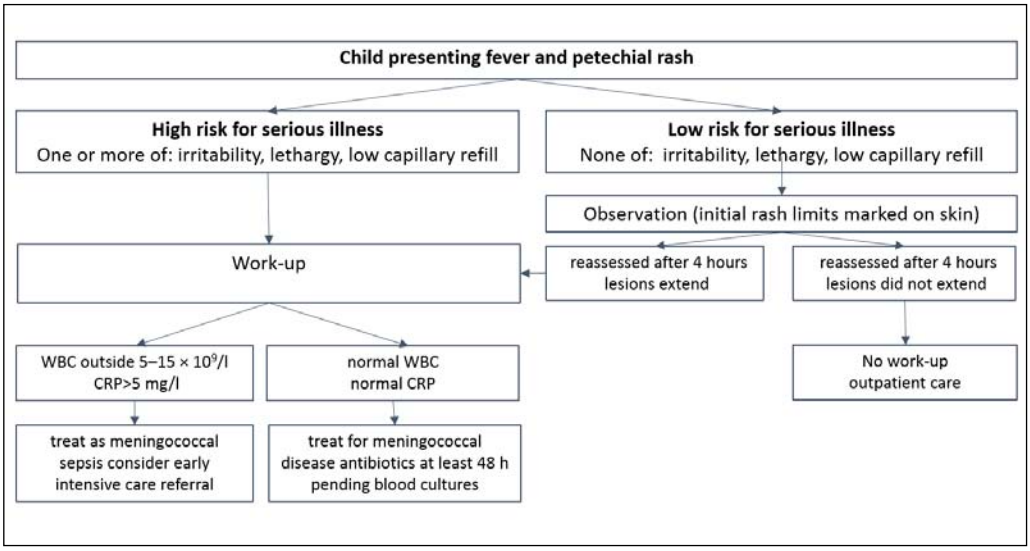

Fig. 1. Management of children presenting with fever and petechial rash in the emergency department

Definitions

Children were classified in two categories: serious illness; non-serious illness. 'Serious illness 'was attributed when children with positive urine/blood/CSF cultures, positive PCR tests from CSF, or focal lesions on chest X-ray. The classification of 'non-serious illness 'was assigned to children whose reference standard tests for serious bacterial infection (chest radiograph, urine / blood/CSF culture) were negative or the tests were not done.

Ethical consideration

Ethical approval was obtained from the Hospital's Ethics Committee. As study procedures consisted of an interview that enabled chart completion by the treating physician, the parent/legal guardian of each participant provided verbal consent. The study respects the Helsinki Declaration regarding confidentiality of data collected.

Statistical analysis

All analyses were conducted using *SPSS 19.0* for Windows. Statistical significance between continuous variables was assessed using student T-test. The $p < 0.05$ was considered statistically significant. We used Spearman rank correlation method. We analysed the sensitivity and specificity of signs, symptoms and testing results for the diagnosis of serious illness. We used Cohen's kappa coefficient to measure inter-rater agreement between variables and the diagnosis of serious illness. We performed binary logistic regression analysis (serious illness=1; non-serious illness=0) for each variable. Variables that reached statistical significance were included in a group model. Binary logistic regression analysis was done for the group model. We calculated the area under the curve for the model to estimate its accuracy.

RESULTS

Out of 7327 children addressing the hospital's Emergency Department, from August 2011 to April 2012, 44 children (0.6%) associated fever with petechial rash at presentation. Table I presents baseline characteristics of 41 children assessed according to the study protocol.

Most children presenting with fever and petechial rash were under 5 years of age (n=29; 70.7%), with a peak between 2 and 5 years (n=17; 41.5%). Female to male ratio was 1:2.4. The most common clinical diagnoses in children presenting with fever and petechial rash were: viral respiratory illness (n=20; 48.8%), upper respiratory tract infection (n=7; 17.1%), pneumonia (n=3; 7.3%); asthma exacerbation (n=3; 7.3%); and gastroenteritis (n=3; 7.3%). Meningococcal disease was found in one case (2.4%). One child presenting with urinary tract infection (UTI) also had infectious mononucleosis.

Spearman correlations between the diagnosis of serious illness and referral (from self/general practitioner/ambulance); onset of rash (day before presentation/day of presentation) were not significant.

TABLE I.

Baseline characteristics, for those with and without a serious illness

	Serious illness n=8	Non serious illness n=33	p value
Age in years, mean (SD)	3.77 (2.5)	3.2 (2.7)	0.958

SD=standard deviation; sec=seconds; ATB=Antibiotics;
CRT=capillary refill time; APTT= Activated partial thromboplastin time

Workup and diagnosis:

Ten children presented with leucocytosis, while one case presented with leucopenia. The anomalies were not correlated with the diagnosis of serious illness.

Erythrocyte sedimentation rate (ESR) was>15 mm/h in 32 children; however, it was poorly correlated to serious illness diagnosis. If using the cut-off ESR=50 mm/h (area under the curve =0.814, p=0.006), 89% of serious illnesses would be correctly identified as such, and 6.1% of non-serious illness would be incorrectly identified as positive. CRP above 6 mg/l was recorded in 6 children (4 in the non-serious illness group and 2 in the serious illness group) and was poorly correlated to serious illness diagnosis. The area under the curve for CRP (area =0.783, p=0.010), using the cut-off of 6 mg/l, shows 33.3 % of all serious illnesses would be correctly identified as such, and 9.4% of all non-serious illness would be incorrectly identified as positive.

Monospot test was positive in a single child. Prothrombin time ranged between 12 and 16.5 probably due to mild dehydration. The activated partial thromboplastin time was in normal range in all children. Platelet count was in normal range for all children.

Table II shows the blood and CSF cultures and PCR in regards to diagnosis.

TABLE II.
Diagnosis based on work-up (CSF, blood culture, PCR)

Total	Class	Initial Diagnosis	CSF culture/PCR	Blood Cultures	Blood PCR	Anti-biotic
Fever and petechiae as initial symptoms n=41	Serious infection n=8	Meningitis n=2	N. Mening. Gr B n=1; enterovirus n=1	N. Mening. Gr B n=1; Negative n=1	N. Mening. Gr B n=1; Negative n=1	n=2
		Pneumonia n=3	-	Negative n=3	Negative n=3	n=3
		Bacteremia n=2	-	gram negative diplococci n=1; Gr A Strep n=1	Negative n=2	n=2
		UTI, mononucleosis n=1	-	Negative n=1	Negative n=1	n=1
	Non-serious infection n=33	Viral respiratory illness n=20	Negative n=5	Negative n=20	Negative n=20	n=10

		Asthma exacerbation n=2	-	Negative n=2	Negative n=2	n=0
		Physical Exertion n=1	-	Negative n=1	Negative n=1	n=0

n=number of patients, URI diagnosis was established after positive results of nasopharyngeal rapid antigen detection tests for group A strep, nasopharyngeal rapid tests for viruses or nasopharyngeal cultures. The antibiotic treatment refers to acute treatment after discharge from emergency department; N. Mening. Gr B= Neisseria Meningitis Group B; Gr A Strep= Group A streptococci

One third of children showed at least 2 signs of the "ILL" criteria. We used Cohen's kappa coefficient to measure inter-rater agreement between variables and the diagnosis of serious illness. Six variables were in significant agreement with the diagnosis of serious illness (kappa value statistically significant - tab. IV): ESR above 50 mm/h, ill appearance, shivering, lethargy, prolonged capillary refill time and back rigidity. These were included in a group model. The area under the curve for the model was=0.907 (CI 95%: 0.765 to 1).

TABLE IV
Sensibility and specificity of significant variables.

Variable	Kappa	p	Sensitivity % Sensitivity CI %	Specificity % Specificity CI %	PPV% PPV CI %	NPV % NPV CI %
Lethargy	0,21	0,05	87,5	50	28	94,74
CI %			47.4 to 97.9	32.9 to 67.1	12.1 to 49.4	73.9 to 99.1
Ill appearance	0,29	0,04	62,5	75	35,7	90
CI %			24.7 to 91.0	57.8 to 87.8	12.9 to 64.8	73.4 to 97.8
Shivering	0,27	0,05	50	80,6	36,36	87,9
CI %			16.0 to 83.9	63.9 to 91.8	11.2 to 69.1	71.8 to 96.5
CRT	0,19	0,03	12,5	100	100	83,7
CI %			2.0 to 52.6	90.2 to 100	16.6 to 100	69.3 to 93.2
Back rigidity	0,19	0,03	12,5	100	100	83,7
CI %			2.0 to 52.6	90.2 to 100	16.55 to 100	69.3 to 93.2
ESR >50 mm/h	0.57	0.00	75	87.9	60	93.5
CI %			35.1 to 96.1	71.8 to 96.5	26.4 to 87.6	78.5 to 99.0

Significant variables were selected if they had a significant Cohen coefficient and reached both specificity and sensitivity above 50%. PPV=Positive Predictive Value; NPV=Negative Predictive Value; CRT= Capillary refill time.Positive Brudzinski sign; seizures; unconsciousness; paresis were not seen in any the patients, thus sensitivity and specificity analysis could not be performed.

Treatment

Most children (58.5%) were discharged from emergency department after a maximum of twelve hours, while 41.4% were admitted in the hospital. Ten children (24.4%) were treated with antibiotics before presentation, but this factor was not significantly correlated with the diagnosis of serious illness. In the emergency department, antibiotics were prescribed acutely in all the children with a diagnosis of serious illness: meningitis (n=2), pneumonia (n=3); bacteraemia (n=2), urinary tract infection (n=1). However, 28.6% (8/28) of children without bacterial infection were also prescribed antibiotics.

DISCUSSION

The majority of children with fever and petechiae in our study who did not have an identified cause for the rash were consid-

ered to be presumably due to viral infections. We documented that from those children addressing the emergency care department in the regional hospital, for fever and petechial rash, 18% had serious illness, while Meningococcal meningitis was found in only 2% of children included in the study. However, Baker et al had found a higher prevalence of meningococcal disease of 7% among children with fever and petechiae (12). Although the prevalence of meningococcal disease was low, the need for triage is high as acute illnesses in children are extremely common(1). Nevertheless, recognition and early treatment of the child with meningococcal disease is vital.

Most of children presenting with fever and rash in our study were males under the age of 5 years. Young age is reported in other studies (13,14), but we did not find other reports showing higher prevalence in males. Clinical signs and laboratory investigations determine management and treatment. In many situations, unnecessary tests or treatments are initiated which could be detrimental to the patient and cost efficient. The significant criteria for diagnosing serious illness, included in our model were: ESR above 50 mm/h, ill appearance, shivering, lethargy, prolonged capillary refill time and back rigidity. This model had good accuracy for predicting the diagnosis of serious illness in our data.

The "ILL" criteria model is largely used; however, this model has several limitations and needs further improvement and revalidation. The accuracy of the ILL criteria in our study was poor. We have found that the 'ill appearance' was a strong predictor for serious illness, nonetheless, this is a subjective interpretation of symptoms/signs. Where physicians need to triage patients and refer them to secondary care if necessary, this 'gut feeling' of 'something is wrong' could prove very useful, summarizing physician's experience (15,16).

In our analysis the C-reactive protein had poor specificity in detecting serious illness in our study. Other studies found that CRP provides moderate information for ruling in/out serious bacterial infection in children with fever at presentation. Asseray et al concluded that the cost generated by CRP examination is not justified (17). The cost of using superior tests, like procalcitonin, for decision making in the association of fever and petechiae in the emergency department, might be more specific but it was not evaluated in our study (18). Our data suggests that using a different cut-off for the ESR might provide higher specificity in diagnosing serious illness.

Antibiotic treatment was prescribed in all cases suspected of bacterial infection, however, at discharge 41% of children, did not have a work-up suggestive for a bacterial illness. Antibiotic overuse promotes the development of drug-resistant bacterial strains, increase treatment failure rates and costs (19,20).

Strengths and limitations of the study

The paper addresses a particular topic of interest to paediatricians and emergency department physicians, as there is a paucity of useful literature regarding clinical decision-making in children presenting with fever and petechial rash. The relatively small number of patients decreases the statistical power of the study. The study did not record the follow-up; thus we were unable to establish the evolution under treatment. Although we did not follow up all patients, we assumed they did not have adverse outcomes, as no patient died and no patient returned to hospital. Details

regarding localization or number of petechial lesions were not noted, which might produce higher predictive value.

CONCLUSIONS

Most children presenting with fever and rash in the paediatric emergency department were under 5 years of age. The most common clinical diagnoses were: viral respiratory illness and upper respiratory tract infection. Meningococcal disease was found in one case. CRP>6 mg/l was poorly correlated with serious illness. The following variables were strongly associated with serious illness: ill appearance, shivering, lethargy, back rigidity, ESR>50 mm/h and prolonged capillary refill time. Most children were treated with antibiotics, however, at discharge almost half of them, did not have a work-up suggestive for a bacterial illness.

Screening for low prevalence but high morbidity conditions, as the meningococcal disease, with an extensive work-up is time and resource consuming and may lead to unmotivated antibiotic use. Larger studies are needed to change the emergency practice for management of fever and rash.

NEWS

EVALUATE THE DIFFERENT RAPID SCREENING TESTS FOR DIAGNOSIS OF LEPTOSPIROSIS

Leptospirosis is a worldwide zoonosis caused by spirochetes of the genus Leptospira. The disease is endemic in some tropical and subtropical region and exposure to infection is widespread. Leptospirosis is characterised by wide clinical variability, ranging from a mild flu-like illness to an acute life threatening condition, but only patients with the symptomatic forms of the disease are hospitalised. Leptospirosis is a common cause of acute febrile illness in tropical climate and must be differentiated from other infection like typhoid, malaria, dengue, scrub typhus, viral hepatitis etc. Early diagnosis of Leptospirosis is important since mortality rate is high in patient with severe Leptospirosis. Diagnosis of Leptospirosis is often made by serological tests. The MAT is the serological test used in reference laboratories because of its high degree of sensitivity and specificity. However, MAT is a complex test that requires significant expertise and large panel of live-cell suspensions, as well as, antibody levels detectable by MAT usually appear after day 6 or 7 of symptoms. Hence, interpretation of the results is difficult and results are usually not available quickly enough for patient management. The early diagnosis of Leptospirosis is now possible by using different serological methods which are available commercially in the market such as an IgM ELISA, an IgM dipstick assay (LDS), latex agglutination test, lepto lateral flow test and the indirect hemagglutination assay (IHA). Therefore, rapid and easy to perform tests have emerged in recent years for the diagnosis of Leptospirosis. Majority of these rapid tests are immunochromatographic or particle agglutination tests. The introduction of such tests in the market needs their evaluation by comparing their results with the gold standard MAT or other tests like IgM ELISA. The present study was to evaluate the usefulness of the diagnostic test kits (leptocheck WB, Latex agglutination test and SD leptospira) for the diagnosis of Leptospirosis by comparing their results with the 'gold standard' test, MAT and IgM ELISA (Panwala T, Rajdev S, Mulla S, et al. To Evaluate the Different Rapid Screening Tests for Diagnosis of Leptospirosis. *Journal of Clinical and Diagnostic Research*. 2015, Vol-9(2): 21-24).

PLATELET INDICES AND LIVER FIBROSIS EVALUATION IN CHRONIC HEPATITIS C (Abstract): Recently, several studies have reported that the mean platelet volume and platelet distribution width may give information about liver fibrosis severity in chronic hepatitis C. **The aim** of the present study was to evaluate whether platelet indices correlate with hepatic fibrosis measured by transient elastography in patients with chronic hepatitis C. **Materials and methods:** Patients with chronic hepatitis C were prospectively enrolled. Samples for complete blood count and routine biochemical parameters were collected and analyzed in the same day with liver fibrosis assessment by transient elastography. Mean platelet volume, platelet large cell ratio and platelet distribution width were compared with stages of liver fibrosis. Statistical analysis was carried out using SPSS 17.0 software. A P-value of less than 0.05 was considered statistically significant. **Results:** There were 139 patients with chronic hepatitis C (70.5% males, mean age 54.8±16.7 years). Compared with mild/moderate liver fibrosis patients, those with advanced liver fibrosis had an increased mean platelet volume (10.4±0.7vs. 10.9±0.9, p<0.002), platelet large cell ratio (28.5±5.3 vs. 32.5±7.2, P<0.0001), and platelet distribution width (12.8±1.5 vs. 14.1±2.7, P=0.003). **Conclusions:** Increased platelet indices were associated with advanced liver fibrosis stages evaluated by transient elastography in patients with chronic hepatitis C. **Keywords:** PLATELET INDICES, LIVER CIRRHOSIS, HEPATITIS C, FIBROSIS, TRANSIENT ELASTOGRAPHY.

Today, chronic hepatitis C virus (HCV) infection affects more than 180 million individuals worldwide, being among the world's leading causes of death and the major reasons for the increasing prevalence of liver cirrhosis and hepatocellular carcinoma (1).

Staging of liver fibrosis is important for the estimation of prognosis, for surveillance and for treatment decisions in patients with HCV. Liver biopsy is still considered "gold standard" for the staging of liver fibrosis in spite of its several shortcomings such as intra- and inter-observer variability in histopatologic interpretation, sampling errors, variable accessibility, and high cost; in addition, it is an invasive procedure, sometimes associated with rare but potentially life-threatening complications (2,3). Therefore, noninvasive methods such as serum fibrosis markers and ultrasound-based elastography have been inten-

sively evaluated for the assessment of liver fibrosis over the past two decades and many of them have proven to be excellent tools for staging fibrosis in patients with chronic HCV (4). Serum fibrosis markers may be used singly (5) or in combination, some of which are patent-protected and commercially available: FibroTest® (6), Fibrometer® (7), ELF® (8), and Hepascore® (9), with no risk for the patient and no contraindication, with interlaboratory reproducibility. The advantage of serum markers is that they are largely available and reproducible; the disadvantage is that they can be influenced by the comorbidities and medications. A simple, cost-free, readily available test in all hospital setting is APRI (AST/platelets ratio) (10). Transient elastography (TE) measures liver stiffness and has highest level of performance among noninvasive methods for diagnosis of advanced fibrosis and cirrhosis (11).

Over the last few years, several studies have evaluated the platelet indices for the assessment of liver fibrosis in patients with chronic hepatitis B virus (HBV) (12,13) and HCV (14). Platelet indices include mean platelet volume (MPV), platelet distribution width (PDW), and platelet large cell ratio (P-LCR). Some studies have reported that MPV and PDW may give information about liver fibrosis severity in HBV and HCV (12-14), although the relationship between these and other platelet indices and liver fibrosis is still controversial (13,15). Recently, Purnak et al. demonstrated that increased MPV is an independent predicting factor for liver fibrosis in patients with chronic HCV (14). However, to our knowledge, the association between platelet indices and liver fibrosis in hepatitis C virus related liver disease remains mainly unknown.

The aim of the present study was to evaluate whether platelet indices correlate with hepatic fibrosis measured by TE in patients with chronic HCV.

MATERIAL AND METHODS

One hundred and thirty-nine patients with known chronic HCV naïve to antiviral treatment and followed-up in a tertiary care center, who have undergone TE examination from January 2013 to June 2014 were prospectively enrolled in this study. Exclusion criteria involved all conditions that are known to modify platelet indices such as chronic liver diseases other than HCV, type 2 diabetes mellitus, hypertension, hypercholesterolemia, obesity, malignancy, and hypochromic anemia (16,17). None of the patients included have received anticoagulant or antiaggregant medications, nonsteroidal antiinflammatory drugs (NSAID) and oral contraceptives before hospital admission because all these drugs could influence platelet aggregability.

The study protocol was approved by the local Ethics Committee, and all patients were consecutively enrolled to the study after providing written informed consent.

Liver fibrosis assessment. All patients had liver stiffness measured by TE (FibroScan®, Echosens, Paris, France). At least 10 valid measurements, a 60% success rate, and an interquartile range of less than 30% of the median elasticity were required for a measurement to be valid. The liver stiffness was expressed in kiloPascal (kPa), and values range from 2.5 to 75 kPa, with normal values <5.5 kPa (18). According to Metavir score, a cutoff value of 8.7 kPa defines mild (5.6-7.1 kPa=F1) or moderate (7.2-8.7 kPa=F2) fibrosis, while values ≥ 8.7 kPa defines advanced fibrosis (8.8-12.5 kPa=F3; ≥12.5 kPa=F4) [19]. In this study

patients were divided in two groups: mild/moderate fibrosis (F1-F2) and advanced fibrosis (F3-F4).

Serum measurements. Samples for complete blood count analysis were obtained by phlebotomy using minimal pressure and collected into a vacutainer tube, containing ethylenediaminetetraacetic acid (EDTA). These blood samples were analyzed within 2 h on automatic blood counter Sysmex XT-4000i (Kobe, Japan). All tests were performed according to the standardized protocols recommended by the manufacturers (17).

For the determination of platelet indices we used an automated hematology analyzer that could overestimate platelet count especially in thrombocytopenic samples compared with the immunological reference method. The platelet indices were derived from the platelet distribution curve obtained from impedance method. It includes MPV that describes the average platelet size reported in femtolitre (fL), PDW defined as the distribution width at 20% frequency level calculated as the standard deviation of platelet volume divided by MPV, and measures the heterogeneity in platelet size. Derived platelet indices are highly specific to the individual technologies, with different analyzers having different reference ranges. As separate feature, the platelet large cell ratio, P-LCR, can be reported specifically on Sysmex analyzers and is the percentage of platelet larger than 12 fL.

Statistical analysis was carried out using the SPSS 17.0 software (SPSS Inc., Chicago, IL, USA). Continuous data were expressed as median and interquartile ranges and categorical data as percentage. Mann-Whitney U test was used to compare groups, with the chi-square test used for categorical variables. A P value of less than 0.05 was considered statistically significant.

RESULTS

Patient characteristics. In the study period there were admitted 658 patients with chronic liver disease, 226 (34.4%) were diagnosed with HCV, and 139 (61.5%) met the inclusion criteria. There was no difference regarding age, sex or severity of liver disease between patients included and those excluded from the study.

Clinical and biochemical characteristics of the patients are summarized in tab. I. There were 139 patients with chronic HCV (70.5% male, mean age 54.8±16.7 years).

The fibrosis spectrum in patients with chronic HCV was as follows: 25 (17.9%) with stage 1, 39 (28.1%) with stage 2, 15 (10.8%) with stage 3, and 60 (43.2%) with stage 4. All the patients with stage 4 liver fibrosis had compensated liver disease, Child-Pugh class A. Of these 9 (15%) were diagnosed with esophageal varices.

Significant increases in serum alanin aminotransferase, aspartate aminotransferase, alkalin phosphatase, and gamaglutamyl transpeptidase, and significant decreases in albumin, hemoglobin, leucocytes and platelet count were observed in patients with advanced fibrosis (F3-F4).

Comparison of platelet indices between the study groups. There was a significant difference regarding the MVP, PDW and P-LCR values between the patients with mild/moderate fibrosis and those with severe fibrosis ($P=0.002$, $P=0.003$, $P<0.0001$). latelets counts were significantly lower in patients with advanced fibrosis compared with those with mild/moderate fibrosis (240.8±52.1 vs. 156.7±75.8, $P<0.0001$) (tab. II).

IQr interquartile ranges, *MPV* mean platelet volume, *PDW* platelet deviation width, *P-LCR* platelet large cell ratio

When all of the patients were considered in the analysis, the strongest and most inverse correlation was found between liver stiffness and platelet count (rs =-0.607, P <0.001), followed by serum albumin (rs =-0.566, P <0.001), and prothrombin time (rs =-0.505, P <0.001). There was also a strong correlation between liver stiffness and spleen size (rs = 0.504, P <0.001), followed by serum ALT, and then by total bilirubin (rs=0.358, 0.335, respectively, P <0.001).

There were no correlations between platelet indices and liver stiffness value measured by transient elastography.

DISCUSSIONS

Liver biopsy is still considered gold standard for the staging of liver fibrosis. However, its diagnostic sensitivity is limited by significant variability of the sampling and histological assessment (small sample size not representative to the entire

liver) (2,3). Furthermore, severe complication such as bleeding, hemoperitoneum, or even death could occur in some patients (20). All these disadvantages make it impractical to assess disease progression by serial biopsies in routine clinical practice (21).

Transient elastography (Fibroscan®) is reproductible, non-invasive and validated test for the assessment of liver fibrosis (11,22). Along with this imagistic method, there are also several direct and indirect markers used alone or in combination, some patent-protected, which have proven excellent methods for staging fibrosis in patients with chronic HCV and HBV (4-7). The advantages of all noninvasive methods include no risk for the patient and no contraindication, widespread availability, easy to perform and repeat in outpatient clinic and at the bedside, well accepted by the patients and thus, can be repeated for longitudinal disease monitoring which is difficult, if not impossible, with liver biopsy (22,24). However, both Fibroscan® and some patent-protected serum markers are still expensive. It was this context that assessment of platelet indices triggered much interest as possible non-invasive, widely available, practically costless serum markers of liver fibrosis in patients with chronic HBV or HCV (12-15, 25, 26). Recently, there have been published several studies on chronic HBV patients, concluding that MPV might be a marker for assessment of liver fibrosis (12). Some studies have suggested that elevated MPV levels may be an independent predictor of cirrhosis (25) or associated with liver disease activity (26) in patients with chronic HBV or portal vein thrombosis (27).

Data on platelet indices and chronic HCV are scanty. Purnak et al (14) demonstrated that MPV is increased in patients with advanced fibrosis, and this marker along with other serological markers could give information about liver fibrosis severity in chronic HCV. The authors demonstrated that patients with HCV had significantly higher levels of MPV as compared to the control group, despite the same number of platelets, concluding that high levels of MPV could represent an indirect early marker of advanced liver fibrosis in such patients.

Our study showed that high platelet indices (MPV, PDW and P-LCR) could differentiate between mild/moderate and advanced fibrosis in HCV patients. These results confirmed some previously mentioned studies including patients with chronic HCV (14). It has been reported that increased platelet indices are directly related with thrombocytopenia, which is a direct reflection of platelet destruction by hypersplenism (28). In advanced stages of fibrosis thrombocytopenia is a multifactorial condition attributed to the sequestration of platelets by the spleen secondary to portal hypertension, reduced thrombopoetin which regulates megakaryocyte maturation and platelet production, and bone marrow suppression (28). All these mechanisms could influence platelet indices, because thrombocytopenia is not only a reflection of platelet destruction, but also of platelet production, especially in advanced chronic liver disease.

Our study has some advantages: such as being the first prospective study that evaluated the role of all platelet indices in patients with chronic HCV, using transient elastography for liver fibrosis quantification. It has also some limitations as relatively small sample size, and lack of evaluation of dynamics of platelet indices. Our

results need to be confirmed by further investigations on larger groups of patients.

CONCLUSIONS

In our study the platelet indices, MPV, PDW and P-LCR are associated with fibrosis stage measured by transient elastography in patients with chronic HCV, and they might be used as markers to evaluate liver fibrosis stage.

INFORMED CONSENT IN PSYCHIATRIC MEDICAL CARE - A PROSPECTIVE QUANTITATIVE STUDY (Abstract): Respecting fundamental ethics principles entails the process of obtaining an informed consent, which is a necessary requirement for offering good psychiatric medical care and conducting research studies on human subjects, who are regarded as the vulnerable population. Presently, in Romania, the informed consent regarding medical interventions is covered by the law of the patient's rights, Law 46/2003, chapter 3. **The aim** of this study is to evaluate the medical staff's perception of the need of the informed consent in the practice of psychiatric medical care. **Material and methods**: This is a quantitative, inquiry based study, with prospective evaluation, based on the responses of 217 medical staff members involved in treating patients with psychiatric disorders. The study unfolded between July 2012 and July 2013, and the questionnaires were answered by medical staff members (psychiatrists, general practitioners, other clinical specialists, psychologists) from Iasi, Botosani, Vaslui, Suceava counties. **Results**: The age group distribution of the medical staff involved in the medical care shows statistically significant differences between the groups questioned (χ^2=227.14; df = 5; p=0.001). Concerning the answers recorded at question no. 2, regarding informing the psychiatric patient, and comparing the studied groups of medical staff, a majority of affirmative answers was noted. **Conclusions**: The medical staff members involved in the patient's treatment recognizes the necessity of a full informed consent when discussing about psychiatric medical care. In psychiatry, the variation of competence raises multiple ethics discussions **Keywords:** INFORMED CONSENT, PSYCHIATRIC PATIENT, MEDICAL STAFF.

The notion of "consent" is frequently encountered in medical records and in specialized literature as "informed consent"; this clarification has the role of emphasizing the informational component of this valid document (1). The informed consent (2) is a very important concept in the relationship between the medical staff and the patient (3). The informed consent is a concept that has developed significantly in the last few years (4). It represents the legal way of validating the respect of personal

autonomy in medical practice and research (5). From an ethics point of view, the informed consent is a necessary stipulation when conducting research and in medical care (6, 7, 8). The consent is a specific legal document, required in written form after the patient has been provided with the complete set of information. The patient must receive information on the necessity of hospitalization, treatment, diagnosis, benefits and on risks involved. The doctor has to use a language that is adequate to the patient's educational level (9). The informed consent is the legal and ethics way by which a patient decides to join clinical research, after having received, understood and analyzed the given information. The decision to participate in the research must be uncorrupted and the informed consent must be signed before the study proceeds (10). Being an ethical and legal request, the informed consent is a documented requested both nationally and internationally, both in research and in medical care (7). The elements of an informed consent are: competence, communicating information, analyzing information, understanding information, voluntary decision (10).

This concept does not have old historical origins, and the written agreement, for both research and medical care, belongs to the modern ideologies of the 20th century (11, 12). Even though these regulations regarding the consent in clinical research have existed since the 19th century, the medical staff was either unaware of them, or ignored them (13, 14).

MATERIAL AND METHOD

This is a prospective questionnaire based study, applied to the medical staff involved in the healthcare of psychiatric patients. The study was conducted between July 2012 – June 2013 and had a research population of 271 members of the staff involved in the therapy of the psychiatric patient: psychiatrist, psychologists, general practitioners, doctors from other specialties (neurologists, neurosurgeons, emergency doctors) from medical centres in Iasi, Suceava, Botosani, and Vaslui. The questionnaires contain questions about the Mental Health Law, the informed consent, providing information, stigmatization, discrimination, confidentiality. The questionnaires followed all the steps from pretesting, revision, validation and application in the final form. The results were statistically processed for each item, subsequently making the correlation of the answers according to different characteristics of the study groups. The Cronbach's alpha value was 0.730, which offers an acceptable result when compared with the threshold of 0.70, and validates the use of the questionnaire to other categories of doctors and psychologists involved in monitoring people with psychiatric disorders.

Amongst the groups of doctors, the frequency distribution analysis according to the specialty highlights the prevalence of resident doctors in the group of doctors with other specialties, and of specialist doctors in the group of general practitioners, while in the group of psychiatrists, a homogeneous distribution can be noticed. The study uses the Kruskall-Wallis nonparametric method for highlighting statistical differences.

RESULTS:

In doctor groups, the distribution analysis according to specialty points out the predominance of resident doctors (54%) for the group of doctors from other specialties and specialist doctors (66%) for the group of general practitioners, whereas the psychiatrists group shows an even distribution. The

application of the Kruskall-Wallis intergroup non-parametric test points out statistically significant differences between the specialty of the doctors who answered the questionnaire (Chi-Square = 15.22; df = 2; p = 0.001).

The groups distribution according to sex shows the predominance of females, sex ratio F/M = 2.3/1. The smallest percentage of females is found in the group of psychiatrists, and the peak frequency is found in the group of doctors with different specialty than general practitioners, but the distribution does not show statistically significant differences when compared to the other groups (χ^2=0.38; df=3; p=0.944).

Concerning age groups, there can be distinguished a higher percentage of subjects questioned with ages between 30 and 39 years of age (49.8%). The distribution by age of the medical staff involved in medical care shows statistically significant differences between the groups questioned (χ^2=227.14; df = 5; p=0.001):

- In the psychiatrists group, most of the subjects have ages between 30 and 39 years old (56.1%), and 12.3% have ages over 60 years of age;

- In the group of doctors with different specialties, subjects in the age group 30 – 39 years old prevail (46%), followed by the under 30 years group (32%);

- 46% of the general practitioners had ages between 30 and 39 years, and 36% had ages in the 40 – 49 years interval;

- 50% of the psychologists had ages between 30 and 39 years and 38.3% between 40 and 49 years.

Concerning answers recorded at question no. 2, affirmative answers in all studied groups were noted when comparing the groups that were studied.

"Do you consider that patients with psychiatric disorders must be informed about the benefits and side effects of the treatment before initiating it?:

a. Yes, the psychiatric patient has the right to an adequate informed consent that has to be followed;

b. In the case of patients with psychiatric disorders, I would provide a minimum of information;

c. The patient with psychiatric disorders must not be informed;

d. I do not know" (tab. I).

TABLE I

Distribution of answers to question no. 2 on the groups studied

Question no. 2	Psychiatrist		Different specialties		General practitioner		Psychologist	
	n	%	n	%	n	%	n	%
Yes	55	96.5%	41	82.0%	41	82.0%	51	85.0%
Minimum info.	2	3.5%	7	14.0%	7	14.0%	8	13.3%
No					2	4.0%		
I don't know			2	4.0%			1	1.7%
Mean rank	98.22		114.20		114.10		110.66	

The mean rank of the answers to question no. 2 did not show any statistically significant differences between the questioned groups (Chi-Square = 6.88; df=3; p=0.076):

- Only 3.5% of the psychiatrists consider that they would provide the minimum of information regarding the therapeutic approach;

- Providing minimum information is

found in 13-14% of each of the other groups questioned;

- In the general practitioners group, 4% do not consider that patients with psychiatric disorders must be informed about the benefits and side effects of the treatment, while in the psychologists' group 1.7% does not know what to answer to this question.

DISCUSSION

The purpose of the study was to assess the perception of healthcare professionals with regard to the need and importance of informed consent in medical care. The process of obtaining a valid informed consent is extremely important in both medical research and psychiatric healthcare. Transposing the informed consent in the medical practice is frequently hampered by difficulties in informing the patient in such a manner for him to understand the information, by spoiling its voluntary character etc. (7). The study shows statistically significant differences between the specialty of the doctors who answered the questionnaire (Chi-Square = 15.22; df = 2; p = 0.001). In psychiatry, the variation of competence creates multiple ethical discussions. An informed consent is valid only when the study's subject or the patient receives all the relevant information and comes to a decision freely (15). The significant impairment of the cognitive functions, especially in patients with certain psychiatric disorders, compromises the minimal conditions necessary for a valid informed consent in most of the cases. Also, there are cases when the informed consent cannot be obtained or the informed consent is invalid for minors, some patients with dementia, patients with mental retardation, patients considered a vulnerable category (16). The ethical controversies in psychiatry regarding the admission, respectively the treatment, are channelled especially on the situations in which the person with the psychiatric disorder cannot give his/her consent (17, 18).

In psychiatric healthcare, the medical staff assigned to a patient with psychiatric disorders should try and obtain the free consent of the patient; however, most of the times, they feel compelled to limit the patient's freedom and use constraint (19, 20). This study shows that for the group of general practitioners, 4% do not consider that patients with psychiatric disorders must be informed. The mental capacity of patients with psychiatric disorders is an issue that raises multiple ethical and legal concerns, especially in cases where coercive measures are required (21, 22, 23). In cases of dementia, depending on the type: Alzheimer disease, vascular dementia or any other form of dementia, severe cognitive impairment is always correlated with incompetence (24). Studies show that for patients with psychiatric disorders, like schizophrenia and depression, at least one of the components of the informed consent is impaired (25). All elements of an informed consent are impaired in patients with schizophrenia (26). In schizophrenia, obtaining a valid consent is a continuous challenge, especially in medical research (27).

Diminished mental capacity is more frequent in patients with psychotic disorders rather than in patients with non-psychotic disorders (28). According to studies, the most important predictor for reduced mental capacity in psychiatric disorders is the absence of awareness of the disease and of the necessity of the psychiatric treatment (29). In the last 20 years a great focus has been directed towards developing tools for assessing mental capacity (31).

According to some studies, factors strongly associated with diminished or absent mental capacity are non-voluntary admission, compulsory treatment, severity of symptoms and certain types of psychoses (22). Patients with psychiatric disorders, who were hospitalized non-voluntarily in psychiatry hospitals, are more frequently associated with reduced or absent mental capacity, when compared to patients who were hospitalized voluntarily (23). Multiple studies demonstrated that the severity degree of the psychiatric pathology (30) is associated with reduced or absent mental capacity (32, 33).

CONCLUSIONS

In this study, the majority of staff members involved in therapy recognize the psychiatric patient's right to be informed. However, a small percentage of the participants, more precisely of the general practitioners, invalidate this right.

In psychiatry, the variation of competence raises multiple ethical discussions. The impairment of cognitive functions, especially in some psychiatric disorders, undermines the necessary conditions for a valid informed consent. The issue of informed consent in psychiatric care is extremely complex.

HUMAN PAPILLOMA VIRUS GENOTYPING IN FRESH HEAD AND NECK TUMORS - OUR FIRST EXPERIENCE (Abstract): A growing number of research papers on the role of HPV in the evolution of head and neck cancers have been published in recent years. In these cancers, the prevalence of HPV DNA varies greatly by study, cancer site and geographic location. The most consistent finding relates to the oropharyngeal cancers, where HPV DNA has been found in 35–50% in developed countries in contrast with the rest of the oral cavity, where HPV/DNA was found in 5–15% of the cases. **Aim**: To implement the HPV genotyping method of fresh head and neck cancer samples in our laboratory. **Material and methods**: Fresh tumor samples 3/3 mm in size were collected from 25 patients with tumors of the head and neck: tongue, lips, base of the tongue, oropharynx, and hypopharynx admitted to different surgical clinics in NE Romania. DNA was purified with *Wizard Genomic DNA Purification Kit*. DNA purity (260/280: 1.86 – 1.98) and concentration (227.5 – 1640.1 ng/µl) were measured using a Nanodrop. HPV genotyping was performed using *Linear Array HPV Genotyping* test (*Roche*) in accordance with manufacturer's recommendations. **Results**: Four (16%) of the 25 patients in the study group were women and for all patients the median of age was 67 (range: 58 – 88 years). More than half of the patients recognized being chronic alcohol and tobacco users. All patients were negative for all 37 HPV genotypes tested with *Linear Array*. We validated our results because on all test strips beta globin (low/high) was detected, and the results for negative and positive controls were within the limits indicated by the manufacturer. **Conclusions**: The genotyping method was validated according to kit instructions. To get a general idea on the prevalence of HPV genotypes in head and neck cancer in our region we tested a very small number of samples. It would be useful to continue this study by testing a larger number of patients and using more sensitive methods, such as HPV E6mRNA, cytology, viral load, and HPV16. **Keywords**: HPV, PREVALENCE, HEAD AND NECK CANCERS, RISK FACTORS, DE-ESCALATION THERAPY.

According to GLOBOCAN 2012 (the project of International Agency for Research on Cancer which provides contemporary estimates of the incidence, mortality and prevalence from major types of cancer, at national level, for 184 countries of the world) Romania ranks second in mortality from larynx, lip, oral cavity and nasopharynx cancer in all-age males (32.4/100,000) among 20 European countries (1). Human papillomavirus (HPV) infection is considered a major prognostic and predictive marker in head and neck squamous cell carcinoma (HNSCC). In these cancers, the prevalence of HPV DNA varies greatly by study, cancer site and study location. The most consistent finding relates to the oropharyngeal cancers, where HPV DNA has been found in 35–50% in developed countries in contrast with the rest of the oral cavity, where HPV DNA is found in 5–15% of the cases (2).

As in cervical cancers, for which many HPV testing techniques have been developed, molecular methods for HPV detection in HNSCC are being evaluated with regard to their sensitivity, specificity and clinical relevance. HPV detection in these tumors is relevant to prognosis even in an already-developed tumor, whereas in cervical cancer, where HPV is the cause of almost all tumors, this information has less clinical relevance (3). The study by van Houten VM et al. showed the "missing" biological link, which clearly demonstrated that high-risk HPVs are indeed responsible for a number of HNSCCs by the detection of HPV DNA in tumor samples, presence of viral E 6 oncogene, detection of wild-type p53 gene, and also by the detection of HPVDNA and E6 in the corresponding lymph node metastases (4).

In NE Romania the burden of head and neck cancers is high as between January 2010 – September 2014 we detected 226 such cases: 119 oral cavity cancers – lips and tongue (age range 39-80 years), 1.68% (12/119) women; 56 larynx cancers (age range 47-58 years), 3.57% (2/56) women; 15 hypopharynx cancers (age range 54-67 years), 26.66% (4/15) women; 36 oropharynx cancers (age range 41-71 years), 5.55% (2/36) women. Most of these patients were diagnosed with keratinizing and nonkeratinizing squamous cell carcinoma (5). Testing of the corresponding FFPE samples for HPV DNA presence is subject of an ongoing research study.

In this study we aimed at optimizing the HPV genotyping method in fresh head and neck tumors, in order to further evaluate the prevalence of HPV in head and neck cancers.

MATERIAL AND METHODS

In the interval July 2014 – May 2015 we collected 25 fresh tumor samples 3/3 mm in size from patients treated for different tumors of head and neck (tongue, lip, base of the tongue, oropharynx, hypopharynx) in different surgical department: ORL, OMF and Plastic Surgery.

The DNA was purified with Wizard Genomic DNA Purification Kit. The procedure involved one step of overnight incubation at 55º C/300 rpm of the tumor sample with EDTA 0.5 M, nucleic lysis solution and proteinase K. The next steps consisted in successive addition of specific reagents (protein precipitation solution, ethanol 70%, rehydration solution) and centrifugation at 14.000 g for 1 and 4 minutes, respectively. After the rehydration solution was added, the DNA was kept in the fridge at 4ºC, and the quantification was performed the next day. DNA purity (260 / 280: 1,86 – 1,98) and concentration (227,5 - 1640,1 ng/µl) were evaluated with the Nanodrop. HPV

genotyping was done with *Linear Array HPV Genotyping* test (*Roche*).

Linear Array HPV Genotyping test was described previously, and it is based on PCR amplification (*Applied Biosystems GeneAmp PCR* System *9700 Thermal Cycler*) and strip hybridization in twincubator (6). At the time of hospital admission, the patients were informed about the study and written informed consent was obtained from all participants. The study protocol was approved by the Research Ethics Committee of the Iaşi University of Medicine and Pharmacy.

RESULTS

Four of the 25 participants (16%) were women and the median of age was 67 years (range 58 – 88 years). More than half of the patients recognized being chronic alcohol and tobacco users. All tested patients were negative for all the 37 HPV genotypes tested with Linear Array. We validated our results because on all test strips beta globin (low/high) was detected, and the negative and positive controls yielded results within the range specified by the manufacturer.

DISCUSSION

This pilot study fulfilled its objective of validating the strips of all tested patients. We have experience with the *Linear Array HPV Genotyping* test, as we correctly used it for genotyping over 1000 women with abnormal Pap test, and were declared "proficient" at the 2010 WHO HPV genotyping proficiency panel. However, when we first attempted to genotype fresh head and neck tumor samples we used *High Pure PCR Template Preparation Kit for DNA* purification. With this kit very low amounts of DNA and impure forms of DNA were obtained, making the validation of the strips impossible. With the *Wizard Genomic DNA Purification Kit* high amounts of pure DNA were obtained.

TABLE I

Comparison of different studies on HPV prevalence according to HPV testing method used (7-16)

Author	Year, country	Type of samples	Method	HPV prevalence / no of testes samples
Garnaes E,	2015, Denmark	tonsillar cancers	next-generation sequencing	58% / 632
Hernandez BY	2014, USA	invasive laryngeal cancers	Linear Array	21% / 148
Tsimplaki E	2014, Greece	oral tongue squamous cell carcinoma	HPV E6/E7 mRNA expression	11.3% /53
Rodrigo JP	2014, Spain	oropharyngeal cell carcinomas	GP5+/6+-PCR	6.1% / 248
De Stefani A	2013, Italy	oropharyngeal squamous cell carcinoma	Linear Array	25% / 52
Ribeiro KB	2011, France, IARC	head and neck cancers	HPV16 E7 DNA,	3.1% /196
Shanesmith R	2011, USA	oropharyngeal squamous cell carcinoma	Linear Array	82.4% / 131
Kingma DW	2010, USA	oral and oropharyngeal squamous cell carcinoma	Linear Array	71.9% / 68

The same method for HPV genotyping (*Linear Array*) was also used by other authors who found differences in the prevalence of HPV in head and neck cancers (7-11). The same great variation in HPV prevalence was found when other molecular techniques were used. As can be seen in Table I, HPV prevalence appears to be higher in the US than in European countries, except for a Danish study which reported a high HPV prevalence using a high sensitivity assay: next-generation sequencing (12-16).

In our study we detected no HPV genotype of all 37 genotypes tested with *Linear Array*, which is a PCR based technique, known to be highly sensitive. A possible explanation for this result could be the epidemiological characteristics of our patients, who are old (mean age – 67 years, range 58 – 88 years) and more than half recognized being chronic alcohol and tobacco users. As no HPV genotype was detected, we could not perform any statistical analysis of the possible risk factors. By comparison, patients with HPV-positive HNSCCs tend to be younger, have a history of less tobacco use and previous exposure to marijuana, and had more oral sex partners as compared to those with HPV-negative carcinomas (17). Also, another possible explanation can be the small number of tested patients, only 25, from 4 surgical departments. In our area, the research on HPV involvement in HNSCCs is quite new and in some situations it is difficult to get fresh samples from surgeons. As in cervical cancer testing, in HNSCC many HPV testing methods are available (PCR/Real Time PCR/Reverse Transcriptase from fresh/frozen/FFPE samples/oral cavity brushing, *in situ* hybridization for HR HPV types, p16 immunostaining, DNA/RNA microarray) (3), and there is a need for a standardized assay to assess the full clinical relevance of the obtained results. Data from recent studies suggest that detection of E6 and E7 mRNA expression in carcinomas is a reason to assume that the virus has been etiologically involved (17). Improved survival in patients with a HPV-positive carcinoma may be related to the type of treatment. Preliminary data from small studies indicate that HPV-positive tumors are more likely to respond to induction chemotherapy and radiation therapy (18, 19). Recent studies found increased survival in HPV/ p16-positive oropharyngeal cancer patients treated with postoperative radiation therapy (21) and suggest de-escalation treatment protocols in these cases (22).

CONCLUSIONS

In this study we aimed at optimizing the HPV genotyping method in fresh head and neck tumors, in order to further evaluate the HPV prevalence in head and neck tumors. With *Linear Array* technique we could continue to genotype head and neck tumor sample and have a significant number of tested patients. Also, younger patients with no history of alcohol and tobacco use should be included in the study. The aim of this testing is to reduce chemotherapy and radiation therapy in case if HPV positive tumors, according to current therapeutic protocols. Also, the use of more sensitive biomarker tests (i.e., E6*I mRNA, p16INK4a, UBC9, microRNA expression profile) would help to correctly classify the different types of head and neck cancers.

CHARACTERISTICS OF RESPIRATORY MECHANICS IN CHRONIC OBSTRUCTIVE PULMONARY DISEASE (Abstract): In chronic obstructive pulmonary disease (COPD) the changes in respiratory thoracoabdominal mechanics result from both hyperinflation and functional and structural skeletal muscle alterations. **Aim:** Evaluation of the particularities of respiratory movement in COPD and identification of inter-relations between respiratory thoracoabdominal mechanics and clinical and functional respiratory status. **Materials and Methods**: This study comparatively analyzed the respiratory thoracoabdominal mechanics recorded by polygraphy, using piezoelectric film belts, in 34 COPD patients and 30 healthy subjects, during rest, and during 6-minute walk test. **Results:** In COPD patients, phase angle between direction of thoracic and abdominal respiratory movements presented significantly higher values compared to the control group, for supine (p=0.023) and sitting position (p=0.001), revealing the presence of paradoxical respiratory movements. Furthermore, phase angle dynamics increased significantly during walking test compared to sitting position (p=0.001). Quantitative difference of end-expiratory pulmonary volume (qDEEL) correlated with pack-years (r=0.372, p=0.03) in supine position, and with body mass (r=0.338, p=0.05) and St. George activity score (r=0.353, p=0.041) during walking test. Rib cage inspiratory contribution to tidal volume ratio (%RCi) inversely correlated with pack-years (r=-0.417, p=0.014) and body mass index (r=-0.344, p=0.047) in supine position, and with St. George activity score (r=-0.345, p=0.046) in sitting position. **Conclusions:** In COPD patient thoracoabdominal mechanics is characterized by paradoxical respiratory movements, more prominent during exercise. The alteration of thoracoabdominal mechanics correlated with St. George activity score, pack-years and body mass. **Keywords:** COPD, RESPIRATORY MECHANICS, PLETHYSMOGRAPHY.

Muscle dysfunction is an important co morbidity in chronic obstructive pulmonary disease (COPD), found in interrelation with bronchial obstruction and lung emphysema, together with these causing alterations in exercise capacity through complex mechanisms, including change in thoracoabdominal respiratory mechanics (1).

Hyperinflation caused by emphysema results in lung ventilation inefficiency, use of accessory respiratory muscles, muscle fatigue and altered respiratory mechanics. On an alternative pathogenic pathway, systemic inflammation from COPD causes structural and functional muscle alterations, skeletal muscle dysfunction, involving intercostals

muscles and diaphragm. These are reflected in clinical, respiratory functional and respiratory mechanical effects (2).

The aim of this study was to analyze the pattern of respiratory movements in COPD and to identify interrelations between respiratory thoracoabdominal mechanics, and clinical and functional respiratory status.

MATERIAL AND METHODS

This prospective, case-control study consisted in a comparative assessment of the respiratory movement patterns in two groups: a group including patients with COPD admitted to the Clinic of Pulmonary Diseases Iasi, and a control group including healthy volunteers.

The subjects in the two groups were thus selected as to match for age, gender and body mass index. Considering the small number of female patients with COPD admitted to the clinic, we limited our research to males.

COPD was diagnosed according to GOLD guidelines (3). Ventilatory function was measured by spirometry, including bronchodilator response assessment. The clinical evaluation included dyspnea assessment using Modified Medical Research Council Dyspnea Scale, mMRC (4), body mass index (BMI) calculation, assessment of quality of life in COPD by *St George's Respiratory Questionnaire* (SGRQ) (5), exercise capacity assessment by 6 minute walking test (6MWT) (6). Smoking status was assessed by calculating *pack-years* index.

Thoracoabdominal respiratory movements were recorded by polygraphy, with the polygraph *SOMNO-check effort Weinmann* (SOMNOcheck® Effort, Weinmann®, Germany), and two piezoelectric film belts, a thoracic belt and an abdominal belt, as follows: 6 minute recording in supine position; 6 minute recording in sitting position; 6 minute recording during 6 minute walking test.

The signals, represented by filtered and scaled respiratory abdominal (AB) and thoracic (RC) wave forms, were processed and analyzed using the software *VivoSense Complex Respiratory Analysis Version* 2.0, from Vivonoetics (Vivonoetics, San Diego, California) (7). This allowed the analysis of the following parameters of the respiratory mechanics:

- Inspiratory tidal volume *(Insp Vol)* and expiratory tidal volume *(Exp Vol);*
  - *Tpef/Te: Time to reach peak expiratory tidal flow over expiration time;*
  - *%RCi, %RCe: Percent Rib Cage Inspiratory/Expiratory Contribution to Tidal Volume Ratio,*
  - *Ph Angle: percentage agreement between direction of RC and AB movements during breath;*
  - *|Ph Angle|: Absolute value of AB-RC Phase Angle;*
  - *Ph Angle (Area): AB-RC Phase Angle* - was computed from Lissajous loops between RC and AB excursions. The sign of the phase angle indicates whether AB is ahead of RC (Ph Angle>0) or behind (Ph Angle<0) (7);
  - *qDEEL: quantitative difference of end-expiratory pulmonary volume;*
  - *Work of breathing.*

Statistical data analysis was done using *Statistical Package for the Social Sciences* (SPSS 16.0) and MedCalc 12.1. Statistical significance threshold was set at p=0.05.

RESULTS

Our study included a group of 34 patients with COPD (mean age 65.4 ± 8.6) admitted to the Clinic of Pulmonary Dis-

eases Iasi and 30 healthy men which served as controls (mean age 61.4 ± 8.5).

- *Assessment of estimated respiratory tidal volumes: expiratory volume (Exp Vol), inspiratory volume (Insp Vol)*

In supine position, respiratory volumes were significantly lower in the COPD group than in the control group, both for expiratory volumes (357.1±142.6 ml in COPD group and 506.2±269 ml in control group, p=0.004) and inspiratory volumes (357.1±143.1 ml in COPD group and 505.7±268.6 ml in controls, p=0.004), respectively.

Respiratory volumes inversely correlated with body mass index in COPD group (r=-0.436, p=0.01). Respiratory volumes dynamics in COPD patients showed a significant increase at transition from supine to sitting position (p=0.027), followed by a significant decrease during walking test (p<0.001).

- *Assessment of the absolute value of AB-RC Phase Angle |Ph Angle|*

In supine position, the percentage value of AB-RC Phase Angle presented significantly higher values in COPD group than in the control group (58.7±43.7 in COPD group and 36.9±32.1 in the control group, p=0.023), revealing the presence of paradoxical respiratory movement in COPD patients. The same was found for the sitting position (44.3±33.4 in COPD group, and 24.1±17.4 in control group, p=0.001).

The phase angle difference between COPD and control group became insignificant during walking test (78.5±38.2 in COPD group, and 60.4±29.9 in the control group, p=0.071).

Phase angle dynamics presented a mild decrease, below statistical significance (p=0.278) at the transition from supine to sitting position, followed by a significant increase, compared to sitting position, during walking test (from 44.3±33.4 to 78.5±38.2, p=0.001) (fig. 1).

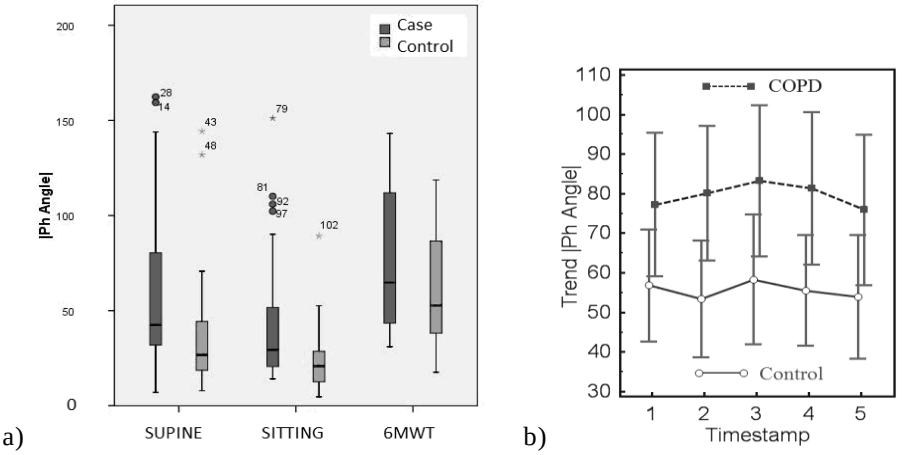

Fig. 1. Phase angle |Ph Angle| in COPD and control group: a) at rest and during 6 minute walking; b) trend during walking test

- *AB-RC Phase Angle assessment: Ph Angle (Area) and |Ph Angle (Area)|*

The parameter |Ph Angle (Area)| showed significantly higher percentage values in COPD group than in the control group, in supine position (59.3±45.6 in

COPD group and 36.5±32.3 in the control group, p=0.03) and in sitting position (43.5±33.5 in COPD group and 23.5±18 in the control group, p=0.001). During walking test, COPD subjects presented significantly higher values of Ph Angle (Area) compared with the controls (19.4±54.2 in COPD group and -5.3±30.4 in the control group, p=0.026). These results revealed the presence of paradoxical respiratory movements in COPD patients.

|Ph Angle (Area)| dynamics in COPD patients presented a mild decrease, statistically insignificant (p=0.244) at the transition from supine to sitting position, followed by a significant increase during walking test, compared with sitting position (from 43.5±33.5 to 77.5±42.3, p=0.001).

- *Quantitative difference of end-expiratory pulmonary volume qDEEL*

The dynamics of qDEEL (expressed in milliliters) in COPD patients showed a mild increase, below statistical significance (p=0.308) during transition from supine to sitting position, followed by a significant increase during walking test, compared to both supine (73.1±34 compared to 32.7 ±27.8, p<0.001) and sitting position (73.1±34 compared to 43.3±27.2, p<0.001). However, an increase in qDEEL during walking test was also found in the control group, the difference between COPD and control group being insignificant (p=0.59).

The value of qDEEL assessed in supine position correlated with pack-years (r=0.372, p=0.03); value of qDEEL assessed in sitting position correlated with body mass in COPD group (r=0.361, p=0.036). The value of qDEEL assessed during walking test correlated with body mass (r=0.338, p=0.05) and *St. George activity score* (r=0.353, p=0.041).

- *Percent Rib Cage Inspiratory Contribution to Tidal Volume Ratio % RCi*

Percent rib cage inspiratory contribution to tidal volume ratio (% RCi) assessed in supine position in the COPD group inversely correlated with pack-years (r=-0.417, p=0.014) and body mass index (r=-0.344, p=0.047).

%RCi ratio assessed in sitting position inversely correlated with *St. George activity score* in the COPD group (r=-0.345, p=0.046).

- *Respiratory rate*

Respiratory rate presented significantly higher values in COPD group than in the control group in supine position (23.3±3.8 min^{-1} compared to 18.9±5.4 min^{-1}, p=0.002), sitting position (24.4±4.9 min^{-1} compared to 18.9±4 min^{-1}, p<0.001) and during walking test (29±4.5 min^{-1} compared to 26.7±6.5 min^{-1}, p=0.017). The transition from resting to walking test resulted in a significant increasing of respiratory rate (p<0.001).

Respiratory rate assessed in sitting position correlated with body mass index (r=0.363, p=0.035). Respiratory rate assessed during walking test correlated with pack-years (r=0.373, p=0.030) in COPD patients.

- *Assessment of inspiratory time: Ti*

Inspiratory time corresponding to supine position correlated to pack-years in COPD group (r=-0.374, p=0.029). Inspiratory time corresponding to sitting position inversely correlated with body mass index in COPD group (r=-0.342, p=0.048). Mean inspiratory time during 6 minute walking test correlated with pack-years in COPD group (r=0.419, p=0.014).

- *Time to reach peak expiratory tidal flow over expiration time: Tpef/Te*

The dynamics of Tpef/Te values in COPD subjects proved similar mean values for supine and sitting position (0.46±0.05 and 0.45±0.03, p=0,918), with a significant increase during walking test, compared with both supine (p=0.001) and sitting

position ($p<0.001$). During walking test the mean value of Tpef/Te was significantly higher in COPD group than in the control group (0.5±0.02 compared to 0.48±0.02, $p=0.002$). Mean Tpef/Te value in supine position correlated with both body mass ($r=0.382$, $p=0.026$) and height ($r=0.620$, $p<0.001$), in COPD patients.

- *Assessment of work of breathing*

Work of breathing presented significantly higher values in COPD group, compared with the control group in supine ($p<0.001$) and sitting position ($p=0.003$), the difference becoming insignificant during walking test ($p=0.174$).

The dynamics of the work of breathing in COPD subjects showed a mild, insignificant decrease during transition from supine to sitting position ($p=0.228$), followed by a significant increase during walking test compared with sitting position ($p<0.001$).

The work of breathing correlated with body mass in COPD patients: in supine position ($r=0.355$, $p=0.039$); in sitting position ($r=0.376$, $p=0.028$); during exercise ($r=0.401$, $p=0.019$).

DISCUSSION

The dynamics of respiratory tidal volume in COPD patients presented a significant increase at the transition from supine to sitting position. This improvement may be explained by a more efficient use of respiratory muscles in sitting position and by a more efficient functioning of the diaphragm.

Exercise represented by 6 minute walking test resulted in a significant decrease of inspiratory/expiratory volumes compared to resting values ($p<0.001$) in both COPD and control group. Tidal volume corresponding to supine position inversely correlated with body mass in COPD group.

Phase angle between thoracic and abdominal movements presented significantly higher values in COPD than in the control group in both supine and sitting position ($p=0.023$ and $p=0.001$, respectively).

Phase angle dynamics in COPD patients showed a mild, insignificant decrease ($p=0.278$) at the transition from supine to sitting position. This decrease of thoracoabdominal asynchrony could explain the tidal volume improvement.

The mean phase angle value progressively increased during walking test in COPD subjects, insignificantly compared to supine position ($p=0.092$) and significantly compared to sitting position ($p<0.001$), but compared to control group the difference became insignificant ($p=0.071$). This observation could be explained by the phenomenon of paradoxical abdominal motion amplification during exercise in COPD patients.

Brennan *et al.* demonstrated paradoxical movements of the lower ribcage in COPD patients, explaining these by an increase in intercostals and accessory muscles activity, in addition with a decrease in diaphragm respiratory activity. These mechanisms seem to be favored by hyperinflation in COPD (8).

From this point of view, Vogiatzis *et al.* have identified two distinct profiles of patients with COPD: one characterized by early hyperinflation during exercise, completely reversible at the end of exercise, and another characterized by late hyperinflation during exercise (9).

Bloch *et al.* showed that lung volume reduction surgery in COPD patients significantly increases abdominal contribution to tidal volume and decreases the duration of paradoxical abdominal movement during inspiration.

The improvement of thoracoabdominal synchronization and the increase of the abdominal contribution to tidal volume dynamics during the respiratory cycle have the effect of decreasing muscle labor during inspiration by a greater participation of

diaphragm in breathing (10).

Quantitative difference of end-expiratory pulmonary volume (qDEEL) did not show significant differences between COPD and control group in supine and sitting position. During walking test, qDEEL mean value progressively increased in COPD group, being significantly higher than in supine ($p<0.001$) and sitting ($p<0.001$) position. However, case-control differences became insignificant ($p=0.59$).

These results confirmed the data obtained by Aliverti *et al*. in a study using optoelectronic plethysmography. These proved an immediate increase of the end-expiratory pulmonary volume in COPD subjects associating lower ribcage inspiratory paradox, and a late increase of the end-expiratory pulmonary volume in COPD subjects without paradoxical movements of the lower ribcage. However, during exercise, dyspnea increased similarly in the two categories of COPD patients. In addition, paradoxical movement did not correlate with ventilatory function and exercise capacity; leg effort increased more markedly in the patients without paradoxical movements (11).

CONCLUSIONS

Thoracoabdominal mechanics in COPD is characterized by paradoxical respiratory movements. In our study the trend of phase angle between thoracic and abdominal respiratory movements revealed a significant increase of thoracoabdominal asynchrony during exercise. At rest, the transition from supine to sitting position resulted in a mild improvement of the thoraco-abdominal synchronism. Thoraco-abdominal breathing movements parameters significantly correlate with smoking (pack-years), physical activity score and body mass in COPD patients: *quantitative difference of end-expiratory pulmonary volume* correlates with pack-years when assessed in supine position, with body mass when assessed in sitting position, and with *St. George activity score* when assessed during walking; rib cage inspiratory contribution to tidal volume ratio inversely correlates with pack-years and body mass when assessed in supine position and inversely correlates with *St. George activity score* when assessed in sitting position; mean inspiratory time during walking correlates with pack-years. Although further research is needed, dual band respiratory plethysmo-graphy by polygraphy could be a helpful and accessible method which can bring valuable information defining the clinical phenotypes of COPD patients.

RELATION OF SERUM HAPTOGLOBIN LEVEL TO ERYTHROPOIETIC ACTIVITY IN BETA THALASSEMIA CHILDREN

Serum haptoglobin (Hp) is a reliable marker for hemolysis. A team of researchers led by Ragab et al investigated the possible relation between Hp depletion and hemolysis severity, hepatitis C virus (HCV) infection and iron load in β-thalassemia children. The study included 22 β-thalassemia major (TM) and 20 β-thalassemia intermedia (TI) children, as well as age and sex matched healthy controls. Pre-transfusion hemoglobin level, serum ferritin, Hp and transferrin receptor levels (sTfR), alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were assessed. Markers of hepatitis C virus (HCV) were determined using PCR. Both patient groups had significantly lower Hp levels compared to the controls, with significant lower levels in TM children. Significant inverse correlations were found between serum Hp and sTfR levels in thalassemia children and among HCV infected patients. The study found that STfR was the only significant independent predictor for serum Hp level. No significant correlation was found between serum Hp and serum transaminases in HCV infected children. The study concluded that serum Hp depletion in thalassemia has a significant relation to the severity of the disease and is correlated with the erythropoietic activity (Ragab SM1, Safan MA2, Badr EA2. Study of serum haptoglobin level and its relation to erythropoietic activity in Beta thalassemia children. *Mediterr J Hematol Infect Dis*. 2015 Feb 15;7(1):e2015019. doi: 10.4084/MJHID.2015.019. eCollection 2015.)

CLINICAL AND EPIDEMIOLOGICAL ASPECTS OF GOUT, A DYSMETABOLIC DISABLING DISORDER (Abstract): Gout is a disease caused by disturbances of uric acid metabolism and it manifests as rheumatic pain with various clinical and developmental issues, but without any major diagnosis problems; it might unfavorably interfere with other metabolisms, especially with carbohydrate and lipid metabolism that interact and erode each other. **Aims**: To provide clinical and laboratory data and to follow the development of gout in patients treated in the clinic. **Material and methods**: The study included 28 patients (25 male and 3 female patients) diagnosed with gout, admitted to the First Clinic of Rheumatology of the Clinical Rehabilitation Hospital Iasi during 2012 - 2013. **Results and discussion**: A new diagnostic method, dual energy computed tomography, was effective in some selected cases of gout, as it may reveal uric acid crystals with specific densities in the damaged joints and periarticular soft tissues. **Conclusions**: Gout is a disorder that occurs when the uric acid produced by the body is stored in the form of crystals in joints and / or soft tissues. In joints, uric acid crystals precipitate and cause inflammatory arthritis that leads to swelling, redness, heat, pain and joint functional impotence. **Keywords**: GOUT, MONOSODIUM URATE CRYSTALS, METABOLIC SYNDROME, DISABLING DISORDER.

Although gout is a disease with a long history (it was described by ancient Egyptians and later by Hippocrates), the relationship between the disease and uric acid was shown in the nineteenth century by Sir Alfred Baring Garrod and it was seen as an acquired metabolic disorder only in 1909 (1,2).

Gout is a chronic disorder closely related to the metabolism of uric acid and to the release of monosodium urate crystals, identified by McCarthy and Hollander in the synovial fluid of inflamed joints (this became the gold standard in the diagnosis of gout). These crystals are deposited in the joints, causing episodic or persistent joint inflammation. They have a key role in understanding the disease. Consequently, local temperature rises, with pain and increased sensitivity of the joint (most often in the joint of the hallux), associated with very intense nocturnal pain (3, 4).

Gout is not merely a metabolic disease where uric acid is deposited in joints and

tissues. It can also induce over time diabetes, atherosclerosis as well as major renal complications (5). Increased production of uric acid is usually caused by a purine-rich diet, by food containing a large amount of fructose or by excessive alcohol drinking, as well as by an increased production, by reduced renal excretion or a combination of these two mechanisms (6, 7). The occurrence of gout is influenced by factors such as gender (gout is more common in men than in women), age (the risk increases after the age of 65), race or diet.

There are some hematological lymphoproliferative and myeloproliferative disorders, hemolytic anemia, cutaneous psoriasis which are characterized by major cell damage associated with hyperuricemia and gout. Gene mutations in enzymes involved in purine metabolism (hypoxanthine-guanine-phosphoribosyltransferase deficiency or increased activity of phospho-ribosyl pyrophosphate synthetase) are known genetic causes of hyperuricemia and gout (7, 8).

Predisposing genetic factors were identified in order to evaluate gout in the general population, with possible therapeutic implications (polymorphism of genes involved in the synthesis of urate transporters in renal proximal tubules) (8). These transport proteins might be seen as pumps for urate, providing the renal excretion of uric acid (ABCG2 - ATP-binding cassette transporter isoform G2; Q141K variant, leading to a two-fold decrease of the urate efflux of and to its intracellular accumulation; URAT1 – one of the essential mechanisms of uric acid reabsorption; NPT1 - sodium phosphate transport protein 1, the protein involved in the tubular secretion of uric acid) (9, 10).

Gout has three stages: *asymptomatic hyperuricemia* - uric acid crystals deposit in tissues; *acute attacks* - crystals deposited in joints cause inflammation, usually in one single joint; *chronic gout* - persistent joint pain and swelling, uric acid deposits in soft tissues (called tophi) are usually located intra or periarticularly in the elbows, fingers and toes or ears. In addition to joint manifestations and tophi formation, renal impairment is one of the most common complications of hyperuricemia (11,12).

Gout is a common rheumatic disease with various clinical and developmental aspects, but it has a quite typical clinical picture, theoretically without major diagnosis problems.

MATERIAL AND METHODS

The study determined the clinical evolution of gout in 28 patients (25/89.28% men and 3/10.72% women) diagnosed with gout, (highly significant difference: $p < 0.005$), admitted to the First Clinic of Rheumatology of the Clinical Rehabilitation Hospital Iasi during 2012 – 2013. The aim was to provide clinical and laboratory data and to follow the development of gout.

The data was gathered using clinical and epidemiological survey forms that recorded age, sex, place of origin, eating and occupational behaviors, co morbidities and associated treatments, family history of gout in relatives of the last four generations, onset signs and development trends etc.

The processing and interpretation of collected data was performed using the Epid SPSS13.0 software and statistical and mathematical tests.

RESULTS AND DISCUSSION

Gout is a common disease in the general population and it is caused by hyperuricemia, which is a major risk factor in the

development of the disease and it is however easy to detect. If hyperuricemia levels are higher than 7 mg / dL, the risk of joint and kidney damage increases also. An attack of gout is caused by the precipitation of uric acid crystals in the synovial fluid. It is a slow process, resulting from persistent hyperuricemia.

The highest frequency of the disease was found in the age range of 51-60 years in men and above 60 years in women, with a sex distribution of 89.28 % male to 10.72 % female.

Differences in age and sex of patients with hyperuricemia are likely related to variations in renal *clearance* of uric acid that are influenced by estrogen and androgen levels (12) (fig. 1).

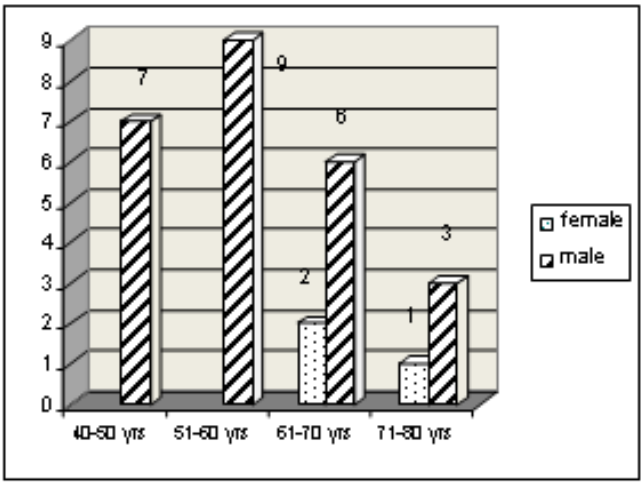

Fig.1. *Sex and age distribution of gout study patients*

Hyperuricemia was positively correlated with male gender, obesity, body size, body mass index, dietary intake of proteins, social status. 6 of the 28 cases (21.42%) had a body mass index BMI of > 25 kg/m^2.

17 of the 28 patients (60.71%) were from urban areas and 11 patients (39.29%) were from rural areas (fig. 2).

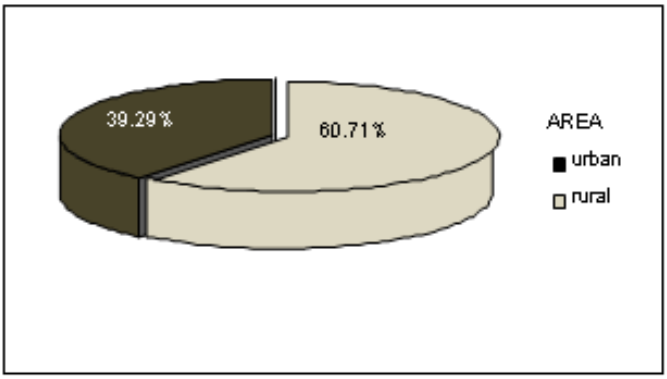

Fig. 2. *Rural / urban distribution of gout study patients*

The epidemiology of gout is closely related to that of hyperuricemia, which is defined as a serum urate concentration higher than two standard deviations above the normal maximum values related to sex, namely, over 7.0 mg / dL (0.42 mmol / l) in men and above 6.0 mg / dL (0.36 mmol / l) in women.

Epidemiological studies have shown a strong correlation between serum urate levels and chronic alcohol ingestion, due to increased production of urate and suppression of the renal excretion of uric acid caused by hyperlactatemia (8,12). In our study, 35.71% of gout patients were chronic consumers of ethanol.

The average duration of the disease at admission was: less than 1 month in 2 cases (10.71%); 1-2 months in 7 cases (25.00%), 2-5 years in 13 cases (46.42%); over 5 years in 6 cases 21.42%.

Our data have also shown that gout has four clinical pictures corresponding to four stages of the disease: asymptomatic hyperuricemia, acute attacks of gout, intercritical period and chronic tophaceous gout.

Rarely, the gout patients did not have a second acute attack. Usually, acute episodes reoccurred between six months and two years after the first attack.

In untreated patients, the acute attacks occurred more often and with more severe symptoms, for long periods, often associated with fever and having a polyarticular character.

Joints were damaged at the onset of gout, as follows: metatarsal phalangeal (MTP I) and proximal interphalangeal (PIP I), bilateral in 3 patients (10.71%); median region of tarsus in 2 patients (7.14%); knees in 9 patients (32.14%) and polyarticular damage in 14 patients (50.00%). The typical attack of gout with sudden onset of intense pain was found mainly in one joint, namely, the metatarsal phalangeal joint; the objective examination showed purple shiny skin, especially in the affected joint; local temperature was increased and cutaneous hyperesthesia was present, increased sensitivity to gentle palpation of the area as well as attempts to mobilize the damaged joint. Signs of lymphangitis were found in some cases (32.14%) and cellulite effusion was rare (7.14%).

In some cases the onset was polyarticular, with damage of knees (26 patients; 92.85%), ankles (23 patients; 82.14%), MTP hallux (14 patients; 50.00%), PIP (8 patients; 28.57%) elbow (12 patients; 42.85%), hand (11 patients; 39.28%), shoulder (3 patients; 10.71%), hip (3 patients; 10.71%).

Usually, the clinical onset of primary gout occurred in a state of full health, either as an attack of acute arthritis or due to a renal colic as the result of uric acid lithiasis. In some cases, the gout of the joints was acute, with extreme paroxysmal pain caused by inflammations. Chronic arthritis was preceded or not by an acute attack.

Recurrent episodes of acute arthritis in MTP are characteristic of gout, but there may be also other causes for this location of arthritis, such as infections, psoriasis and other crystal deposition arthropathies (7, 8).

Over 50% of patients may have arthritis in another location, which is less specific for the first attack of gout – temporomandibular, acromioclavicular, sternoclavicular, manubriosternal, sacroiliac, pubic symphysis, femoral hip; it may be accompanied by flexor tenosynovitis associated with carpal tunnel syndrome (9,10).

The less acute polyarticular manifesta-

tions are not rare. Therefore it is important to detect monosodium urate crystals in the synovial fluid of the affected joints in order to diagnose gouty arthritis when there is no clear cause of the disease.

Musculoskeletal ultrasound shows good results in the ability to detect crystal deposits and other characteristics of gouty arthropathy. Recently, specific elements of gouty arthropathy were described in the literature: hyperechoic image of the external surface of hyaline cartilage - the so-called sign of "double contour" (12), hyperechoic areas in the synovial fluid, with the appearance of "soft" or "hard" tophi (13).

A new diagnostic method, dual energy computed tomography, was effective in some cases of gout, as it may reveal uric acid crystals with specific densities in the damaged joints and periarticular soft tissues (3).

Extraarticular manifestations are present in structures rich in proteoglycans, as they have a high susceptibility to develop tophi, due to their high affinity for sodium urate. Thus, 6 patients of the study group (21.42%) had gouty tophi localized in the pinna, fingers and toes, knees, olecranon bursa, Achilles tendon. In 2 patients with chronic tophaceous gout (7.14%) - pseudorheumatoid form – the skin covering superficial tophi was pressed and ulcerated, leading to the drain of a white pasty substance composed of sodium urate crystals.

Renal lithiasis was identified by ultrasound in 9 patients (32.14%), who had hyperuricemia for long periods of time (> 9 mg %) and high levels of uricosuria.

In the 28 cases, laboratory examinations showed during the acute episode the following data: uric acid values between 6-7 mg % and 9 mg; uricosuria values < 0.4 g / 24 h (14.28%); 0.4-0.8 g / 24 h (17.85%); 0.8-1 g / 24 h (3.57%); > 1 g / 24 h (28.57%); these examinations were not carried out in 10 cases.

Dyslipidaemic syndrome was found in 7 cases with high cholesterol levels (25.00%); in 11 cases with high triglyceride levels (39.28%), in 7 cases with high levels of total lipids (25.00%) and in 3 cases with diabetes mellitus type II (10.71%).

Serum uric acid during the acute episode may be normal and measuring hyperuricemia levels is not a prerequisite for diagnosis. Hyperuricosuria was present in 32.14% of patients.

Radiological changes in the acute stage of the disease included the swelling of the periarticular soft tissue, juxtaarticular osteoporosis, joint space narrowing. In 9 patients (32.14%), radiological lesions indicated the development of secondary arthrosis, as osteophytes, subchondral osteosclerosis or significant clearing of joint space were found.

Treatment is aimed at eliminating the monosodium urate crystals. Joint inflammation resolves after their removal and the disease can be considered cured. Serum uric acid levels should be maintained indefinitely within normal limits, in order to prevent the formation of new crystals and the relapse of gout attacks (9).

It is important to treat arthritis because it can occur at any time, even after the treatment started and it can persist for as long as the crystals in the joints remain undissolved. The prevention of episodes of arthritis may be achieved using anti-inflammatory drugs that reduce mild subclinical inflammation caused by the presence of monosodium urate crystals in joints.

The presence of gout may indicate also the presence of metabolic syndrome or of some of its components (hypertension, dyslipidemia, obesity, glucose intolerance), which should be also recognized and treated (14).

The treatment of evolving gout aims at stopping the acute attacks and preventing the relapses, reducing the levels of hyperuricemia and treating complications and comorbidities.

Patients in the study group received early treatment of acute gouty arthritis that solved the inflammatory phenomena as rapid as possible by delivering a non-steroidal anti-inflammatory drug for the remission of the inflammatory phenomena (0.5 mg, 1-3 times / day). The treatment of recurrent episodes of arthritis, gouty tophi or nephrolithiasis was made, in order to avoid lesions of the cartilage and bone and the development of tophi.

Uricase theray is an option for the treatment of hyperuricemia in gout, but its use is limited due to side effects. In humans, the uricase may decrease the level of uric acid by 0.78 mg/dL after 4 hours of administration. Rasburicase, a recombinant uricase, was successfully used in severe cases of gout. It is delivered in a monthly single dose, due to the development of tolerance after multiple doses.

All non-steroidal anti-inflammatory drugs (NSAIDs) were effective for the treatment of gouty attacks. Studies show that naproxen (500 mg two times a day) has similar effects as prednisone 35 mg / day (32, 33). Gastrointestinal, cardiovascular and renal adverse effects are the main reasons for limiting the use of NSAIDs in the treatment of gouty arthritis. A short course of 30-40 mg prednisone for 2-4 days proved to be effective in the treatment of gouty arthritis (8).

The most common drug used to lower serum uric acid is allopurinol, an inhibitor of xanthine oxidase, which is an enzyme involved in the metabolism of purines into uric acid (11).

Febuxostat is used in patients intolerant to allopurinol and in gout patients with renal failure, as it is a selective inhibitor of xanthine oxidase, which is metabolized in the liver.

Pegloticase is a new drug approved in the USA in 2010 for the treatment of gout resistant to conventional therapies. It is a drug obtained from a porcine recombinant enzyme.

CONCLUSIONS

The study group showed multiple comorbidities, especially diabetes mellitus, hypertension, dyslipidemia, obesity.

Hyperuricemia was positively correlated with male gender, obesity, body size, body mass index, dietary intake of protein, social status.

Our data have also shown that gout has four clinical pictures corresponding to four stages of the disease: asymptomatic hyperuricemia, acute attacks of gout, intercritical period and chronic tophaceous gout.

The risk of developing articular manifestations of gout or tophi is related to duration of hyperuricemia, sex and age of the patient. Both gouty arthritis and tophi are minor manifestations which are fully treatable and reversible; therapy should be initiated on onset; however, renal impairment is more severe and sometimes irreversible, so that early diagnosis and treatment is required.

A better evolution and prognosis of

gout may be achieved through close cooperation between patient and doctor, by providing early and effective treatment, in order to prevent osteoarticular and renal lesions.

All these correlations found in practice and also reported in the literature show that gout is a complex metabolic nosological entity, characterized mostly by rheumatic manifestations.

OUTCOMES OF PULMONARY REHABILITATION IN SEVERE PULMONARY HYPERTENSION - CASE PRESENTATION (Abstract): Chronic pulmonary artery hypertension (CPAH) is characterized by progressive increase in vascular resistance and pulmonary artery pressure, leading to right heart failure and death. Diagnosis algorithm is complex, and the underlying cause often remains undefined. We present the case of a 74-year-old male patient, whose diagnosis was disputed for several months between cardiologists and pulmonologists, being eventually diagnosed with severe pulmonary hypertension and hypoxemic respiratory failure of chronic thromboembolic etiology intricate with diffuse interstitial lung disease. The new therapeutic approach with riociguat failed and the treatment was stopped, then the patient addressed Iasi Pulmonary Rehabilitation Clinic for an inpatient pulmonary rehabilitation program, comprising functional assessment, nutritional and psychological counseling, mild inspiratory muscle training sessions, low workload endurance exercise, followed by relaxation and appropriate breathing techniques. After two weeks, oxygen saturation, shortness of breath, fatigue, sleep, anxiety and depression symptoms had improved while 6-minute walk test distance did not change significantly. **Keywords**: PULMONARY HYPERTENSION, RESPIRATORY FAILURE, PULMONARY REHABILITATION.

Chronic pulmonary artery hypertension (CPAH) is a debilitating disease of the pulmonary vasculature, characterized by progressive increase in vascular resistance and pulmonary artery pressure, leading eventually to right heart failure and death. Diagnosis algorithm is complex, and the underlying cause often remains undefined.

The current treatment strategy for CPAH patients includes three main steps, the initial approach including physical activity, supervised rehabilitation, and psychosocial support while pharmacological therapy is indicated only as a second step, according to the vaso-reactive or non-reactive type of CPAH and determinants of prognosis (1, 2, 3, 4). Pulmonary rehabilitation and supervised exercise, added to

pharmacological treatment options increase exercise capacity and quality of life of these patients, although there are small cohort trials proven otherwise (5).

CASE REPORT

We present the case of a 74-year-old male patient, with a complex medical history, who was admitted in November 2016 to the Pulmonary Rehabilitation Clinic of the Iasi Rehabilitation Hospital for an inpatient pulmonary rehabilitation program, his major complaints being severe dyspnea, fatigue, sleep disturbances, and an overall diminished quality of life and physical function while under long-term oxygen therapy at home. The patient was a former mild smoker (5PY) and not exposed to respiratory hazards.

Clinical examination revealed oral cyanosis, telangiectasis, splitted second heart sound left parasternal 2nd interspace, severe regurgitation murmur in tricuspid area, BP = 100/60 mmHg, arrhythmic heart sounds (HR = 95/min), oxygen saturation SpO_2 = 88% in ambient air, with no sign of pulmonary or systemic congestion, no finger clubbing.

His past medical history has recorded a diagnosis of prostatic adenocarcinoma Gleason 5, eight years ago, under hormone therapy for seven years, discontinued by the urologist due to occurrence of progressive shortness of breath, fatigue, and weight loss (10 kg in 9 months), leading to repeated hospitalizations in pulmonology and cardiology services.

The case was disputed for several months (May-September 2016) between cardiologists and pulmonologists, being eventually diagnosed with severe pulmonary hypertension (precapillary type) and hypoxemic respiratory failure, following the recommended algorithm (1) (tab. I).

TABLE I

Diagnostic approach and results

Investigation	Results
Echocardiography	Dilated right chambers, PAPs estimated = 86 mmHg; mild systolic dysfunction RV, moderate functional and pulmonary tricuspid regurgitation, normal LV, mild to moderate mitral regurgitation, without hemodynamic significance
ECG, Holter	Atrial flutter with variable conduction
Bodypletismography, Spirometry & DLCO	FVC = 120%, FEV1=123%, FEV1/FVC = 78,47%, MEF50 = 130,5%, TLC = 121,8%, RV = 134,5% (normal values), DLCO = 42,7% from predicted values (fig.1)
Chest X-ray	Bilateral diffuse interstitial opacities
CT of the chest	Bilateral ground-glass opacities, fine subpleural reticular opacities, several mediastinal adenopathies, and three nodular peribronchial opacities
Lung perfusion scan	Multiple segmental perfusion deficits (moderate-severe) (fig. 2)

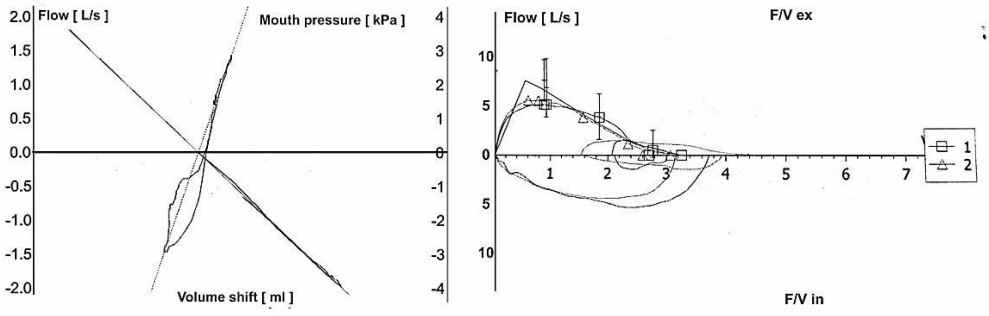

Fig. 1. Body pletismography and flow-volume loop showing normal values for pulmonary volumes and flows

Etiology of CPAH was supposed to be chronic thromboembolism possibly intricate with diffuse interstitial lung disease (idiopathic pulmonary). Due to the diagnosis of post embolic pulmonary hypertension distal type, associated with inoperability, in June 2016 the patient has started treatment with pulmonary vasodilator riociguat 1 mg tid for 2 weeks, then 1.5 mg tid but after one week he has developed paroxysmal nocturnal dyspnea, leading to reassessment of treatment and etiology of PAH, the pulmonary interstitial lung disease being now considered the leading culprit and only diuretic and anticoagulant treatment was continued (August 2016).

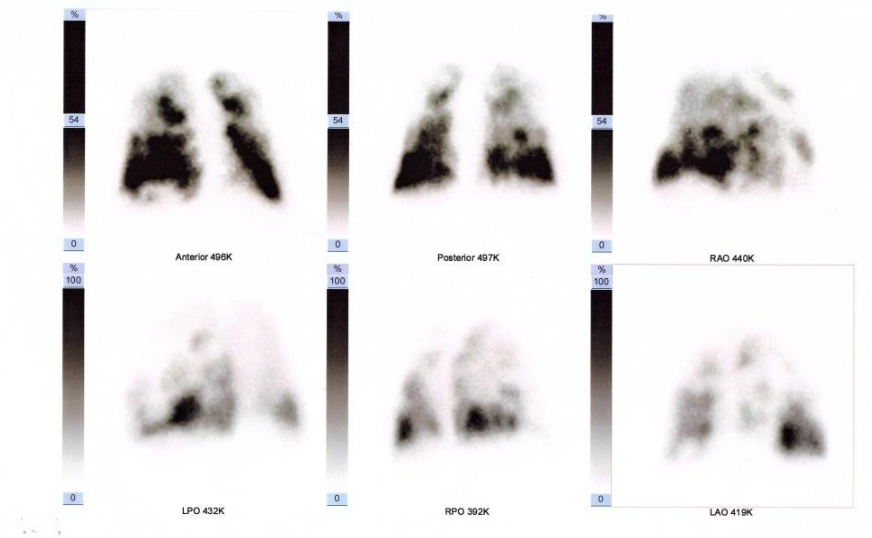

Fig. 2. Multiple segmental perfusion deficits (moderate-severe) in lung perfusion scan (chronic thromboembolism intricate with diffuse interstitial lung disease)

During admission in Iasi Respiratory Rehabilitation Clinic, the patient has followed a comprehensive respiratory rehabilitation program, comprising functional assessment, nutritional and psychological counseling, mild inspiratory muscle train-

ing sessions, low workload endurance exercise, followed by relaxation and appropriate breathing techniques (6, 7, 8, 9). After two weeks, oxygen saturation, shortness of breath (assessed through Borg and mMRC scales), fatigue, sleep, anxiety and depression symptoms had improved while 6-minute walk test (6MWT) distance had no significant improvement.

DISCUSSION

This case is particular through diagnosis difficulties of CPAH and as a consequence etiologic treatment had not the anticipated beneficial results. Prognosis indices are represented by clinical evidence of right ventricle failure, the progression of symptoms, WHO class and 6MWT distance (10, 11). Unsolved thromboembolic obstruction in the pulmonary arteries leads to group 4 pulmonary hypertension, according to World Health Organization. Pulmonary endarterectomy is the treatment of choice for chronic thromboembolic pulmonary hypertension as potentially curative therapy, but about one-third of patients, including our case, are not suitable candidates for the surgery, either due to distal and inaccessible nature of the lesions or comorbid conditions, requiring pharmacologic treatment options (12).

Riociguat is a member of the therapeutic class of soluble guanylate cyclase stimulators, associated with significant improvements in 6-minute walk distance, pulmonary vascular resistance, and time to clinical worsening (13, 14), being the only agent approved for treating both chronic thromboembolic hypertension and pulmonary arterial hypertension. The novel mechanism of riociguat lies in its ability to restore the homeostatic and therapeutic effects of nitric oxide that are diminished because of phenotypic alterations associated with pulmonary hypertension (14) but in the presented case it seemed to have no positive results, questioning the vascular etiology of CPAH.

On the other hand, several small size randomized controlled trials reported that trained CPAH patients have decreased fatigue and dyspnea, higher level of physical exercise, improved distance to 6MWT, quality of life, and cardiorespiratory function (15, 16) but the optimal method of exercise, intensity, and duration of the training are still under debate. Because of the positive outcomes, pulmonary rehabilitation was introduced in the recent guidelines of treatment and management of PAH. A low workload endurance exercise and weightlifting training under close medical supervision, thorough patient education regarding his disease, nutrition, and the safe level of exercise were recommended (1, 17).

In the clinical case discussed above, the initiation of pulmonary rehabilitation was relatively late, and outcomes were negatively affected by the unclear cause of the PAH, rapid evolution of the symptoms, and the negative prognosis of the main underlying disease.

Still, features demonstrating an improved quality of life as the diminished severity of dyspnea, improved sleep pattern, and psychiatric symptoms of depression and anxiety were displayed after two weeks of a comprehensive rehabilitation program.

CONCLUSIONS

Our study highlights that the core issue of the multidisciplinary approach to complex clinical cases of pulmonary hypertension remains the close cooperation between cardiologists and experienced pulmonary rehabilitation experts, to improve outcomes and ultimately, survival of these severely impaired patients.

CUTANEOUS MANIFESTATIONS ASSOCIATED WITH THYROID DISEASE (Abstract): **Aim:** To present the clinical and laboratory features of patients with dermatologic disorders associated with thyroid diseases, diagnostic criteria, type of administered treatment and its effectiveness. **Material and methods**: This study is a retrospective study based on the medical records of patients with thyroid diseases admitted to the Dermato venereology Clinic of the Iasi "Sf. Spiridon" University Emergency Hospital between January 1, 2012-December 31, 2013. Data on clinical manifestations, methods of investigation, therapeutic approach, and associated dermatologic and systemic diseases were reviewed. **Results**: A total of 38 patients were enrolled in this study of which 36 females and two males. An high incidence of cases with autoimmune thyroiditis (63%), followed by polynodular goiter (26.3%) and hypothyroidism (10.7%) was found during the study. The identified dermatologic disorders associated with thyroid diseases were in order of frequency *alopecia areata* (22%), followed by *lichen planus* (18%). **Conclusions:** This study demonstrates that there is a significant association between certain dermatologic disorders and thyroid diseases, requiring periodic thyroid function tests. **Keywords**: THYROID DISORDERS, CUTANEOUS MANIFESTATIONS, AUTOIMMUNE THYROIDITIS

Thyroid disorders are recognized for their involvement in all systems of the human body, and the skin is no exception. Some skin changes and dermatologic disorders may be the first symptoms of thyroid disease.

Some studies have suggested that thyroid hormones play a pivotal role in the embryonic development of the skin, as well as in maintaining normal skin function in adult skin (1).

Skin changes occur both in hyperthyroidism and in hypothyroidism. In hyperthyroidism the skin is soft, moist, and

warm associating hyperpigmentation (diffuse, localized or Addison disease) or palmar erythema. Heat is due to increased skin blood flow and peripheral vasodilatation, which can also lead to flushing and palmar erythema. Hyperhidrosis more marked on the palms and soles may be present. In hyperthyroidism hair is described as soft, fine with or without non-scarring alopecia. The presence of thyroid hormone receptors in dermal papilla and external epithelial sheath has been demonstrated (2).

In hypothyroidism, the skin tends to be pale, both because of dermal mucopolysaccharides and dermal water content. The increased dermal carotenoid levels cause a yellow discoloration of the palms, soles and nasolabial sulcus. The most characteristic clinical sign of hypothyroidism is generalized myxedema resulting from the deposition of hydrophilic mucopolysaccharides in the dermis, especially hyaluronic acid and chondroitin sulfate. The skin may appear edematous, dry, pale as wax and firm to touch. Hair in hypothyroidism is coarse, dry, brittle, with reduced diameter, showing an increased tendency to fall, often resulting in partial alopecia (2, 3).

The term of thyroid ophthalmopathy is currently used but the disease process involves the orbital and periocular soft tissues with secondary effects on the eye. Thus, Thyroid-associated orbitopathy (TAO) is a more appropriate definition. The ocular manifestations of TAO can coincide or even precede other systemic complications and include superior eyelid retraction, periorbital edema with secondary proptosis, conjunctival injection and chemosis and impaired ocular motility. While ocular involvement is usually not threatening vision excepting the very severe cases of exposure keratopathy, compressive optic neuropathy and ocular hypertension almost 20% of the patients consider the ocular morbidity in TAO more troublesome than the systemic complications of dysthyroidism (4).

Some skin conditions and diseases with predominantly cutaneous manifestations were associated with thyroid dysfunction or presence of thyroid antibodies. These conditions can be grouped into connective tissue disease (systemic lupus erythematosus, scleroderma, Sjogren's syndrome, dermatomyositis), bullous dermatoses (bullous pemphigoid, pemphigus vulgaris, pemphigus foliaceus, herpetiform dermatitis), pigmentation disorders (melasma, *vitiligo*) and other diseases (*alopecia, lichen planus, granuloma annulare*) (5).

The aim of this study was to present the clinical and laboratory features of patients with dermatologic disorders associated with thyroid diseases, diagnostic criteria, types of administered treatment and their effectiveness based on the study of the patients admitted to the Iasi Dermatology Clinic in the interval January 1, 2012- December 31, 2013.

MATERIAL AND METHODS

This is a retrospective study of the patients with thyroid diseases admitted to the Dermatology Clinic of the Iasi "Sf. Spiridon" University Emergency Hospital in the interval January 1, 2012- December 31, 2013. Data on clinical manifestations, methods of investigation, therapeutic approach, and associated dermatologic and systemic diseases were reviewed.

A total of 38 patients, 36 females and 2 males, were included in the study.

The study was based on patient medical records and photos. Based on the obtained data the patients were grouped according to distribution by age, sex, area of residence, socioeconomic status, clinical features,

association with other diseases, type of administered treatment and its effectiveness.

RESULTS

Between January 1, 2012-December 31, 2013 at the Dermatology Clinic of the Iasi "Sf. Spiridon" University Emergency Hospital of the total of 7672 admissions, 38 patients were admitted for dermatologic disorders associated with thyroid diseases. Thus, the prevalence of thyroid diseases was 0.5%. Based on the obtained data we found that the prevalence of thyroid diseases had increased each year as follows: from 28 in 2012 to 34 in 2013. In the study group thyroid diseases were more common in the rural population (58% *vs.* 42%), corresponding to a ratio of 1: 1.36. A higher frequency of thyroid disorders was found among female patients (95%).

The age of the study patients ranged between 14 and 79 years, most patients belonging to age groups 50-60 years (31.8%) and 60-70 years (21%) (fig. 1).

During the study an increased incidence of the cases with autoimmune thyroiditis (63%), followed by polynodular goiter (26.3%) and hypothyroidism (10.7%) was noted. Of the 24 cases with autoimmune thyroiditis, 11 cases presented hypothyroid status and 13 cases euthyroid status, no cases of autoimmune thyroidopathy with hyperthyroid status being recorded.

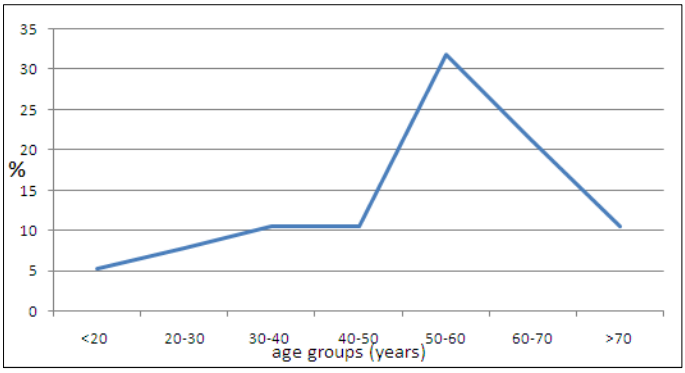

Fig.1. Age group distribution

Thyroid diseases are accompanied by various skin manifestations. In this study these manifestations were: xerosis, xanthelasma, keratoderma, oncho-dystrophy and oral candidiasis. Given the predominance of thyroid dysfunction with hypothyroid status, xerosis was the most common manifestation (45.8%) (fig. 2).

In the study certain dermatologic disorders associated with thyroid pathology were identified. There was an increased incidence of *alopecia areata* (7 cases, accounting for 22% of all skin disorders associated with thyroid diseases) followed by 6 cases (18%) diagnosed with *lichen planus* and 4 cases each (12%) with chronic urticaria and psoriasis (12%). There were 3 cases (9%) of *lupus erythematosus*. Also, *vitiligo* and scleroderma were found in a similar percentage as *lupus erythematosus*, 9% respectively. The lowest incidence of skin diseases associated with thyroid disease was recorded for *pemphigus vulgaris* (1 case), *pemphigus foliaceous* (1 case) and *granuloma annulare* (1 case), accounting for 3% of the cases.

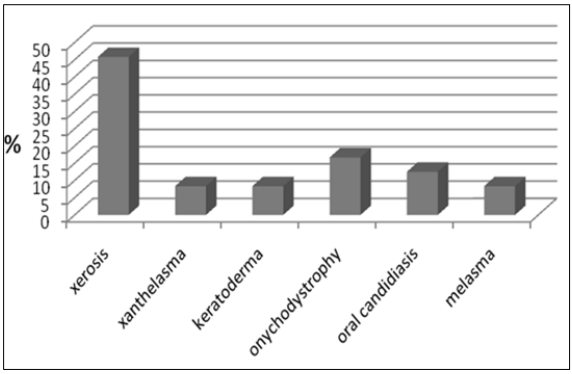

Fig. 2. Skin manifestations associated with thyroid disease

The youngest age at onset of *alopecia areata* in our patients was 19 years and the oldest age at onset 68 years, the age group over 40 years being most commonly affected (71%). There was a higher frequency of alopecia in women (86%) (fig. 3).

Fig. 3. One female patient with alopecia universalis

The association of *lichen planus* with autoimmune diseases is well-known; in this study 6 cases with different clinical forms and anatomical locations being found. The most common anatomical sites were the oral and anogenital regions. The role of autoimmune pathogenesis is supported by the association with numerous autoimmune diseases; in our study of the 6 cases of *lichen planus* associated with thyroid diseases 3 cases were associated with *vitiligo*. The youngest age of patients with *lichen planus* was 39 years and the oldest age 65 years, most cases in age group 40-60 years and with a female predominance (86%). Of the 6 cases of *lichen planus*, 3 cases were associated with autoimmune thyroid disease with euthyroid status, 3 cases with polynodular goiter and 2 cases with autoimmune thyroid disease with operated nodules.

Of the 38 study patients only 3 were diagnosed with *vitiligo* associated with autoimmune thyroiditis. The age ranges were 39-65 years, with a female predominance. In the 3 cases diagnosed with *vitiligo* the associated thyroid diseases were: euthyroid autoimmune thyroiditis (2 cases) and autoimmune thyroiditis with hypothyroid status (1 case).

Age of patients with scleroderma ranged from 53 to 73 years. All three patients were females. Thyroid diseases associated with scleroderma were autoimmune thyroiditis with hypothyiroid status (2 cases) and polynodular goiter (1 case).

Of the 38 cases with thyroid disease anti thyroid antibodies were positive only in 5 of the 7 patients with *alopecia areata*, 2 of the 3 cases with *vitiligo*, 1 of the 4 cases with psoriasis, 1 of the 3 cases with scleroderma, 2 of the 6 cases with *lichen planus* and one case diagnosed with *granuloma annulare*. Antithyroid antibodies were positive in all patients diagnosed with systemic *lupus erythematosus* and chronic urticaria, and in patients with pemphigus antithyroid antibodies were not measured.

All patients were systematically evaluated by an ophthalmologist and none of the signs mentioned above were noticed. A degree of mild conjunctival injection and dry eye symptoms could be noticed and were treated with topical medication.

The treatment was individualized for each patient depending on associated diseases. As there are no cases of hyperthyroidism, only hypothyroid patients were treated. Levothyroxine replacement therapy was initiated depending on thyroid hormone levels, no treatment being administered to euthyroid patients. Of the 38 patients, 18 were received levothyroxine. To the treatment of thyroid disease was associated the treatment of skin disease.

DISCUSSION

The prevalence of thyroid diseases at the Iasi Dermatology Clinic is 0.5%, much lower compared with literature data according to which the prevalence is estimated to be 2-5% (6, 7). Our data are in agreement with the data in the literature according to which all ages are affected by thyroid disease, with a peak incidence between 35 and 65 years.

The prevalence of *lichen planus* (16%) is similar with that reported in the literature. Kreuter et al. (8) conducted a retrospective study and found that 15.4% of patients with atrophic *lichen sclerosus* presented an associated autoimmune disease. 16.3% of patients with atrophic *lichen sclerosus* had a thyroid disease of Hashimoto thyroiditis and Graves's disease type and positive anti thyroid antibodies in 9.4%.

It has been reported that patients with chronic spontaneous urticaria also have associated autoimmune diseases, particularly autoimmune thyroid disorders such as Hashimoto thyroiditis. Several studies have shown that a significant number of patients (33%) had elevated anti thyroid antibody levels (9, 10), whereas in our study group this percentage was of only 12%. Compared to the literature, the incidence of cases with of psoriasis vulgaris at the Iasi Dermatology Clinic was higher than that reported in a study on 1236 patients, 12% *vs.* 1.77%, respectively (11).

CONCLUSIONS

This study demonstrates that there is a significant association between certain dermatologic and thyroid disorders, requiring periodic thyroid function tests.

NEWS

INCREASED THICKNESS OF ABDOMINAL SUBCUTANEOUS ADIPOSE TISSUE OCCURS MORE FREQUENTLY IN STEATOHEPATITIS THAN IN SIMPLE STEATOSIS

The incidence of obesity is increasing and contributes to the rising incidence of fatty liver. Body mass index (BMI) is used to assess the degree of obesity but does not take into account the pattern of body fat distribution. The incidence of fatty liver disease, both nonalcoholic steatohepatitis (NASH) and simple steatosis, is increasing in the Western world. In a large autopsy study of obese patients and controls, a 6.2% incidence of NASH was found. The need to distinguish between NASH and simple steatosis is essential; as patients with NASH can go on to develop portal hypertension and cirrhosis. Body mass index (BMI) is commonly used to define overweight and obesity but does not predict the presence of NASH or simple steatosis. Despite a normal BMI, patients may still develop nonalcoholic fatty liver disease (NAFLD), especially if they have a more prominent abdominal distribution of their adipose tissue. Thicker abdominal subcutaneous adipose tissue is associated with steatohepatitis, but not simple steatosis, also for patients with BMI below 25 kg/m2. There is good correlation between abdominal subcutaneous adipose tissue thickness and BMI. A trend noted in this study is that patients with NASH died at a younger age. Fibrocongestive splenomegaly, despite the absence of cirrhosis, may occur in some patients with steatohepatitis (Fiel MI, Sima HR, Desman G, et al. Increased Thickness of Abdominal Subcutaneous Adipose Tissue Occurs More Frequently in Steatohepatitis than in Simple Steatosis. *Arch Pathol Lab Med*. 2013; 137: 642–646).

PACHYDERMODACTYLY- ROLE OF LOCAL CORTICOTHERAPY

PACHYDERMODACTYLY- ROLE OF LOCAL CORTICOTHERAPY (Abstract): Pachydermodactyly is a rare skin disease, defined as a benign form of digital fibromatosis. It is clinically characterized by painless hypertrophy of the skin around the proximal interphalangeal joints of the fingers, more common in males. This rare condition can affect both hands and is often associated with mechanical injury of the skin. Although there is no specific therapy, cessation of mechanical trauma associated with topical corticosteroid therapy can lead to satisfactory results. We present 3 sporadic cases of classical pachydermodactyly, anatomopathologically confirmed by the presence hyperkeratosis and acanthosis, which responded favorably to topically applied corticosteroids under occlusive dressings. **Keywords**: FIBROMATOSIS, PACHYDERMODACTYLY, STEROID THERAPY

Included in the category of superficial fibromatoses, pachydermodactyly defines a skin condition characterized by painless swelling of the tissues around the proximal interphalangeal joints of the fingers, as shown by its name (gr. *pachy* = thick, *derma-atos* = skin, *dactylos* = finger).

Pachydermodactyly is more common in males (male/female ratio 3/2). Clinically it is characterized by hypertrophy of the dorsolateral aspects of the fingers (especially the index, middle, and ring fingers), most often bilateral and symmetrical. The hypertrophic changes are progressive and limited to the skin around the proximal interphalangeal joint, the affected skin segment presenting no other changes (1).

Pachydermodactyly was first described by Bazex in 1973, and until 2014 only 150 cases have been reported worldwide, but the total number is certainly higher, many of them not being yet reported (2).

The medical literature describes cases of pachydermodactyly associated with carpal tunnel syndrome, Dupuytren's contracture, gynecomastia, varioliform macular atrophy, thyroid dysfunctions, Ehlers-Danlos syndrome, but the most common association is with local microtrauma. Based on these findings, Bardazzi *et al.* (6) described five clinical forms of pachydermodactyly:

- classic - associated to mechanical trauma and affecting more fingers;
- localized or monopachydermo-dactyly;
- familial;
- extended to the metacarpophalangeal joints and dorsal aspect of the hand;
- symptomatic - associated to tuberous sclerosis;

CASE REPORT

We present 3 sporadic cases of classic pachydermodactyly in male children aged 8, 11 and 13 years, two of them living in rural and one in urban area. The disease was diagnosed one year earlier, and the patients were monitored at the Dermatology Clinic of the Iasi "Sf. Spiridon" University Emergency Hospital (fig. 1).

Fig. 1. Skin changes around the proximal interphalangeal joints

The children presented to the clinic with asymptomatic, diffuse thickening of the skin around the proximal interphalangeal joints of fingers II-IV, bilateral in two cases and unilateral in one case. Physical examination revealed the absence of joint pain and local warmth.

Case history showed that the changes occurred many years ago, being caused by repetitive micro trauma related to farm work in which rural children take active part and also to the habit of rubbing the hands together associated especially with emotional states, behavior noticed by their parents before the occurrence of symptoms.

Laboratory tests ruled out an autoimmune-mediated inflammatory disease, the biological, biochemical and immunological tests being within normal ranges. Also, X-rays of the hands showed no joint abnormality and secondary nuclei normal for age (fig. 2).

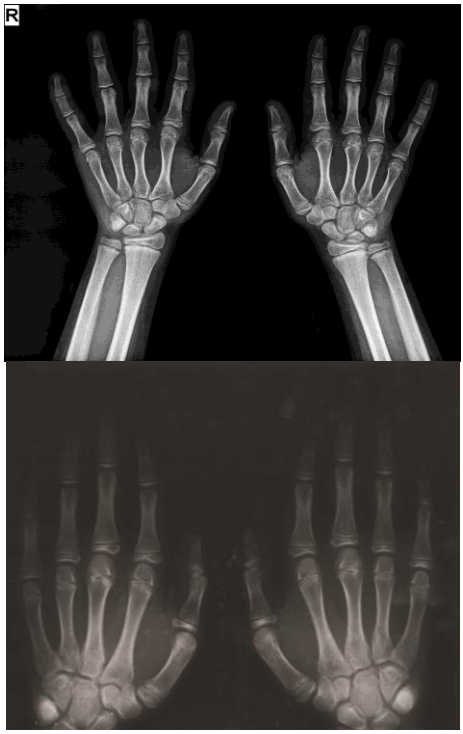

Fig. 2. X-ray image

Comparative ultrasound assessment of the hands denied the presence of any abnormal collections within the radiocarpal, metacarpophalangeal, and proximal interphalangeal joints, and appearance of normal extensor tendons, without tenosynovitis.

The clinically evident deformities around the proximal interphalangeal joints were solely due to skin thickening. At this level, skin thickness was 3.4 mm, compared to 0.7 mm in the unaffected areas on the dorsal aspect of the wrist (5-fold higher). The thickness of the scalp was also measured, and as it was normal a diagnosis of pachydermoperiostosis (Touriaine-Solente-Gale syndrome) was ruled out.

Together, the clinical and imaging findings made the diagnosis of pachydermodactyly, subsequently confirmed by histopathological examination, which revealed irregular thickening of the skin with slightly elongated dermal papillae, acanthosis and discrete spongiosis (fig.3); the corneous layer exceeded the thickness of the epidermis and the granular layer was prominent (fig. 4); there was extensive collagenization of the dermis, and fat glands and lobules were divided by thick connective tissue septa (fig. 5, 6).

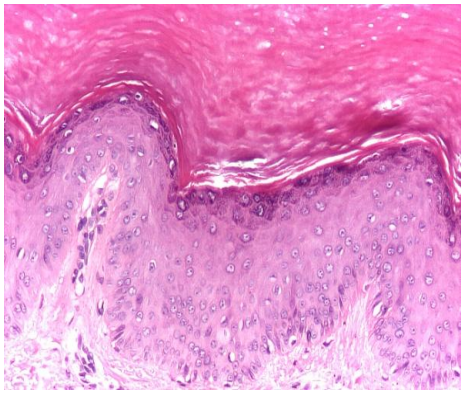

Fig. 3. Irregular epidermis with prominent granular layer, HE, x 4

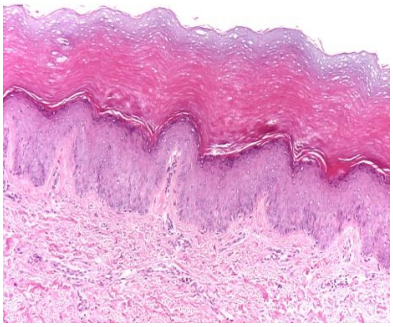

Fig. 4. Keratin crust thicker than epidermis, HE, x 4.

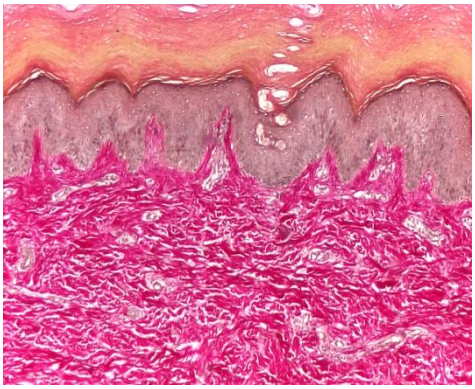

Fig. 5. Marked collagenization of dermis, VG, x 4

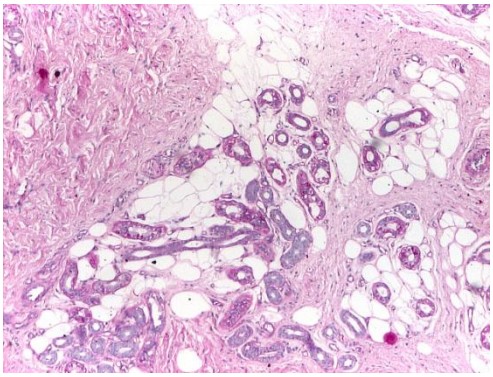

Fig. 6. Fat lobules divided by connective tissue septa, PAS, x 4

In all three cases, the performed investigations, particularly pathological examination, allowed us to differentiate the lesions from lesions with similar symptomatology, such as pachydermoperiostosis, juvenile chronic arthritis, rheumatoid arthritis, gout (gouty tophi), lichen myxedematosus, psoriatic acropachy-dermodactyly, acromegaly, fibrosarcoma, arthritis of the fingers (Heberden nodes), and joint involvements associated with endocrinopathy.

Caught in an early stage of disease, the patients had a positive response to topical corticosteroids, other invasive therapeutic procedures not being necessary. The described changes were classified as having the same degree of soft tissue injury even if in children with bilateral involvement they were present in a greater number of fingers. Potent topical corticosteroids under occlusive dressings (8-10 hours/day for 3 weeks, then a decreased frequency of applications) were used.

Psychological counseling (both child and parents), focused on the discontinuation of the habit of rubbing the hands together in situations of mental or emotional distress and teaching new relaxation techniques aimed at correcting this behavior, was also recommended.

The course was favorable, improvements being obtained after the first weeks of local corticosteroid therapy (fig. 7).

Fig.7. Hand appearance after local corticosteroid therapy

DISCUSSION

Pachydermodactyly is regarded as a localized form of superficial fibromatosis that mostly affects young adult with a mean age of 21.2 years according to Sagransky. Most commonly, the changes occur on the dorsal and lateral aspects of proximal phalanges of the index and middle fingers, with symmetrical involvement of both hands (3, 4, 5).

The mechanisms involved in the pathogenesis of this disease are not fully understood, some authors claiming that it is induced by repetitive minor local trauma. In this respect, Sagransky *et al*. (4) reported 2 cases of pachydermodactyly in poultry processing plant workers handling a significant amount of chicken per days at a fast pace. Other authors suggest as a possible mechanism the habit of rubbing the hand together, which in time leads to diffuse skin thickening and hyperpigmentation along the metacarpophalangeal joints.

The clinical features and especially a history of repetitive trauma are enough to make a diagnosis of pachydermodactyly, but histopathologic findings are useful in excluding other diseases with similar manifestations.

Male gender, and childhood or adolescence, are major contributing factors in the clinical expression pachydermodactyly.

Thus, histopathologic examination is not necessary for making the diagnosis since the diagnosis of pachydermodactyly is clinical; however it can support the diagnosis by revealing an increase in dermal collagen with variable degrees of hyperkeratosis and acanthosis. The dermis is thickened, with coarse collagen bundles, slight fibroblast proliferation, increased fibroblastic activity, and sometimes collagen deposition around sweat glands. The association of acanthosis with dermal thickening is not specific but characteristic of pachydermodactyly and is a useful criterion to distinguish pachydermodactyly from other similar diseases such as keratoderma, where dermal thickening is not present, or fibromatosis, where epidermal changes are usually absent (7).

Caught in the early stages, the patients responded favorably to local corticosteroid therapy, the dermatocorticosteroids proving their efficacy through their anti-inflammatory effects and ability to inhibit cell proliferation and collagen synthesis (8).

The anti-inflammatory effect of corticosteroids is due to the inhibition of the release of phospholipase A2, enzyme responsible for the synthesis of prostaglandins, leukotrienes and other arachidonic acid derivatives; corticosteroids also inhibit transcription factors such as activator protein-1 and nuclear factor-*kB*, involved in the activation of proinflammatory genes (lipocortin and *p11CBP* (calpactin binding proteins). Their immunosuppressive properties consist in the suppression of the synthesis and effects of hormonal factors involved in the inflammatory response, thus inhibiting the migration of leukocytes to the site of inflammation and interfering with the functions of endothelial cells, granulocytes, mast cells, and fibroblasts. The antiproliferative role is exerted through inhibition of DNA synthesis and mitoses, partially explaining the therapeutic action of these agents in dermatological diseases (9).

The efficacy of topical corticosteroids depends on their potency and degree of skin penetration, their activity being is closely related to the ability to bind to a specific receptor in the cytosol, and also to the vehicle into which it is incorporated.

In addition to local action, important is the systemic absorption of topical corticosteroids. Systemic absorption depends on the pharmacokinetic properties of the molecule, as well as on the integrity of stratum corneum and the presence/absence of inflammation; thus, topical agents applied on the skin or mucous membranes have increased absorption if the skin surface is injured or covered by an occlusive dressing (10).

Skin absorption occurs via diffusion of the dermatocorticoid in the stratum corneum. Hydrophilic steroids have a higher penetration rate through the stratum corneum than the hydrophobic ones, while keratinocytes are penetrated more rapidly with lipophilic agents, which explain the multitude of clinical effects of dermatocorticosteroids. After diffusion in keratinocytes, corticosteroids bind to the glucocorticoid receptor in the cytoplasm, inducing the cascade of reactions from which the mediators of messenger RNA synthesis result. The binding capacity of the glucocorticoid receptor in the cytoplasm is greater the lipid solubility of the dermatocorticosteroid is higher. In the human body there are many cells that contain receptors for glucocorticoids, thus explaining the receptor-mediated effects of

glucocorticoids (11).

In the use of local corticosteroids, a rather important problem is the phenomenon of tolerance, which could require a discontinuous drug administration schedule, using a double dose every two days. Another problem is withdrawal, which can be avoided, as in the case of systemic corticosteroids, by progressively spaced applications, or maintaining everyday applications but using a lower potency topical corticosteroid. Also to keep in mind are the complications, occurring especially when potent local corticosteroids (classes 3 and 4) are used; these include skin atrophy, stretch marks, purpura, delayed wound healing, rosacea, pigmentation disorders, and the most frequent systemic complications are hypothalamic-pituitary-adrenal axis suppression and Cushing's syndrome.

CONCLUSIONS

This case report presents the management of three cases of pachydermodactyly, rare entity, with an favorable outcome at local corticotherapy. Its purpose is to attract attention to the importance of clinical findings and minimal non-invasive investigations that can make the diagnosis of pachydermodactyly, and could avoid unnecessary costs incurred by sophisticated imaging investigations or inappropriate therapies.

CHARACTERISTICS OF CO INFECTION WITH HEPATITIS B VIRUS AMONG ROMANIAN PATIENTS INFECTED WITH HUMAN IMMUNODEFICIENCY VIRUS (Abstract). **Aim:** To determine the epidemiological and viroimmunological features and outcome of HIV/HBV-co infected patients cared in the Iasi HIV/AIDS Regional Center. **Material and Methods**: This retrospective study included 252 patients diagnosed with HIV infection and associated hepatitis B virus (HBV) infection assessed at the Hospital of Infectious Diseases in the interval 2000-2013 and treated with antiretroviral drugs active against both HIV and HBV. **Results**: The prevalence of HIV/HBV co infection was 19.9%. A slightly higher frequency of this co infection was found among males (53.2%); most patients belonged to age group 20-29 years (86.5%), mean age was 25.56 years. The predominant route of transmission was parenteral (58.5%), followed by heterosexual transmission (40.1%). The mean CD4 cell count was 246.20 cells/mm^3, in over 41% of cases CD4 count ranging from 200 to 499 cells/mm^3. The mean HIV plasma viral load was 142,906 copies/ml. ALT levels varied between 10-323 IU/l, average 49.90 IU/l, over 65% of subjects having pathological levels. In 21.8% of the cases, total cholesterol was very high, and in 16.8 % of the patients the serum triglyceride levels were below the reference range (160 mg %). **Conclusions**: Our results suggest that HIV-positive patients, chronic hepatitis B infection has a high incidence, especially in younger age groups and is correlated with significant degrees of immunosuppression. **Keywords:** HIV/HBV CO INFECTION, VIROLOGICAL RESPONSE, IMMUNE RESPONSE, ART.

Infection with human immunodeficiency virus (HIV) continues to be a major health problem, the average number of people infected worldwide by the end of 2011 being approximately 34 million. Although the introduction of effective antiretroviral therapy resulted in a significant decrease in the number of deaths related to acquired immunodeficiency syndrome (AIDS), with the extension of life expectancy liver disease has become the most common cause of death among HIV-infected patients, accounting for 14 to 18% of all deaths in this population (1, 2, 3).

Worldwide, hepatitis B is the leading cause of chronic liver disease, accounting for up to half of all cases of cirrhosis and hepatocellular carcinoma; it is estimated

that approximately 400 million people are infected with hepatitis B virus (HBV), most cases occurring in regions in Asia and Africa, where the virus is endemic (4).

Due to the common routes of transmission, HBV and HIV infections coexist in about 3-6 million people worldwide, the prevalence of chronic HBV infection being 10 times higher in HIV-infected people than in the general population (5). HBV/HIV co infection rate mostly depends on the affected community and HBV transmission route, which differs depending on the geographic area (6,7). The prevalence of HIV/HBV co infection in Europe is about 9% (8), while in Romania it reaches about 35-37%, much higher than the European average (9, 10).

HBV infection is considered an opportunistic infection in HIV-infected patients, the co infection with these two viruses causing complex interactions. HIV infection modifies the natural history of chronic hepatitis B by enhanced replication of HBV and higher serum HBV DNA levels, lower rates of HBsAg and HBeAg seroconversion, increased fibrosis, and faster progression to liver cirrhosis (11, 12). HBV may accelerate immunodeficiency and the course of HIV infection by a direct activation of HIV replication and induction of a state of persistent immune activation (13).

This study aimed to describe the epidemiological and viroimmunological features and the course of chronic HBV infection and to determine its prevalence in the HIV-infected patients receiving care and treatment in the Iasi Regional HIV-AIDS Centre.

MATERIAL AND METHODS

This retrospective study (2000-2013) included 252 patients (female 46.8%, male 53.2%, mean age 25.6 years) with HIV/HBV co infection receiving care and treatment in the Iasi Regional HIV/AIDS Centre.

The epidemiological, clinical, and treatment data were collected retrospectively from patients monitoring and clinical records.

The followed parameters were: epidemiological (mode of transmission, age, gender) viroimmunological (dynamics of CD4 and HIV plasma viral load), metabolic (transaminase, total cholesterol and triglyceride levels), and therapeutic. CD4 count was determined by flow cytometry according to CDC classification, and differentiated into < 200, 200-499, and ≥ 500 cells/ml. The evolution of HIV viremia was followed, the undetectable HIV viral load (viral suppression) being based on the analysis of the lower limit of quantification (HIV RNA 50 copies/ml).

Co infection with HBV was defined as the persistence of positive HBsAg in at least two determinations at a minimum interval of 6 months, including the cases of chronic infection and inactive HBV carrier status. The patients with HCV infection or HBV/HCV and HBV/HDV co infection were excluded to avoid possible interactions.

Highly Active Antiretroviral Therapy (HAART) was defined as a combination of at least three antiretroviral (ARV) drugs, including the association of two nucleoside reverse transcriptase inhibitors with either a protease inhibitor, or with a non-nucleoside reverse transcriptase inhibitor. Particular attention was paid to the therapeutic history of drugs active against HBV replication used to treat HIV infection: lamivudine (3TC), emtricitabine (FTC), tenofovir (TDF).

The evaluation and interpretation of the

results was based on the frequency and structure indicators processed with *SPSS* statistics using Student t-test, χ^2 test, Pearson correlation coefficient and the linear trend. P values 0.05 were considered significant.

RESULTS

Over the 14-year study period, the 1358 HIV-infected patients cared and treated in the Iasi Regional HIV/AIDS Centre had periodic serologic testing for HBV; HBsAg was present in 252 of them; thus, the incidence of chronic hepatitis B was 19.19%.

In our series, HIV/HBV co infection was slightly more common among males (53.2%); in terms of age group distribution, as expected, most patients were in the age group 20-29 years (86.5%), the proportion of patients under age 19 and over age 50 being lower. Mean age was 25.56 years, range 6-59 years, with a wide coefficient of variance (40.07%) (tab. I).

In most patients (58.5%) HIV infection was transmitted by parenteral routes, followed by heterosexual transmission (40.1%); 2.4% of HIV infections occurred through homosexual contact, and transmission through injecting drug use was not reported.

TABLE I

Gender and age -group distribution

Characteristic	Number	%
Male sex, *n* (%)	135	53.2%
Age years ≤ 19	1	0.4
20-29	218	86.5
30-39	15	6.0
40-49	15	6.0
50-59	3	1.1
Median age (yrs.)	25.56	

According to CDC classification, most of the study patients were in advanced stages of HIV infection: 46.82% stage C, 34.9% stage B, and 18.25% stage A.

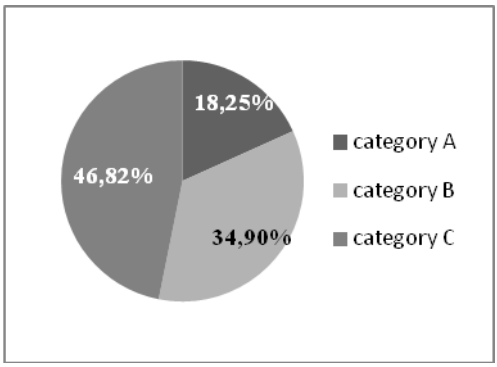

Fig 1. Baseline CDC clinical category of HIV infection

A large number of patients had a significant degree of immunosuppression with a CD4 lymphocyte count < 200cells/mm³ (48.4%) while > 500 cells/mm^3 were found in only 10.3% of the study patients. The individual CD4 count ranged from 3 to 1069 cells/mm^3, with an average CD4 count of 246.20 cell/mm^3.

HIV viral load ranged from undetectable, in 18.3% of the subjects, to a maximum of 4,600,000 copies/ml. About 26.2% of the cases had plasma levels above 100,000 copies/ml, the average viral load being 142,906 copies/ml (tab. II, fig. 2).

Hepatic cytolysis syndrome was a parameter constantly followed throughout the study: 65% of subjects had alanine aminotransferase (ALT) levels above the reference limit (32 IU/ l) and 36.1% exceeded the mean value of 49.9 IU/l in the study group.

The following metabolic abnormalities, common in HIV-infected patients, were found in the study patients. Thus, total cholesterol levels above the reference limit were found in 21.8% of subjects, while the

individual levels of serum triglycerides ranged from 11 to 256 mg%, average 130.72 mg%.

There were a small percentage of cases that had no indication for treatment, while over 98% of patients required antiretroviral therapy, fact accounted for by the age of the study group, most of them being multiple treatment-experienced patients. It is worth mentioning that all HIV/HBV-co infected patients received antiretroviral therapeutic agents with dual action against HIV and HBV, 92.3% receiving lamivudine alone or in co formulations, in only 3.6% of the cases the therapeutic option being tenofovir (fig.3).

TABLE II

Characteristics of patients with HBV/HIV co infection

Characteristic	Number	%

DISCUSSION

High rates of HBV infection have been described among HIV-infected population worldwide, and the risk of HBV-associated end-stage liver disease appears to be increased in HIV-co infection; thus, for a specific serological surveillance and proper initiation of treatment very important is to estimate its regional prevalence (14).

Our study provides the first information on hepatitis B co infection among the population infected with the HIV in Northeastern Romania. Our data show a prevalence of 19.19%, lower than that reported by two previous studies conducted in our country (10, 15), possibly because they included a selected population of HIV-infected children and adolescents, respectively. Our study emphasizes that HIV-infected patients are at a 2.5 - 3 times higher risk for HBV infection compared to the general population of Romania.

The epidemiology of HBV/HIV co infection is complex and incompletely elucidated, and co infection rates depend on the prevalence of HBV infection in the general population and the dominant transmission routes of HIV infection (16, 17). The epidemiology of HIV infection in Romania is unique in Europe as almost all cases are attributed to horizontal transmission, nosocomial, of the virus during early childhood. In our study population study, co infection was mainly associated with this mode of transmission, sexual transmission being prevalently recorded during the last 5-7 years of the study. Our study showed that intravenous drug use, a known risk factor for co infection is virtually absent in the cohort of HIV-infected patients in Northeastern Romania (17). Surprisingly, this did not lead to a significantly lower rate of co infection compared to other HIV populations in Europe with a much higher rate of

intravenous drug use (18).

A statistical association regarding the risk factors for HBV infection showed a higher prevalence in the age group 20-29 years, a known and observed fact in our country, due to the higher risk of exposure to the two viruses by parenteral route. The predominance of male gender was also observed, as described previously in many population groups, probably because of more frequent exposure to risk factors involved in transmission, especially sexual contact with a greater number of partners.

The significant percentage of patients in advanced stages of disease compared with other studies can be explained on one hand by the epidemiological characteristics of HIV infection in our country, most patients being part of the cohort of long-term survivors, on the other hand by the possible influence of HBV on the acceleration of HIV disease progression (19,20).

The lack of a significant immune response against HBV is reflected in the average levels of transaminases which showed pathological levels in more than half of HIV/HBV- co infected patients in the study group.

A limitation of our study is the lack of a complete set of serological markers of HBV and other important parameters such as HBV viral load and HBV genotype. Due to limited financial resources, in many countries HBsAg remains the only widely available test for the diagnosis of chronic hepatitis B in HIV-infected patients. Another limitation may be due to the retrospective design of the study that enrolled mostly compliant patients with good adherence to ARV therapy, coming for regular checkups.

CONCLUSIONS

In this study provides new insight into the current epidemiology and clinical features of HBV/HIV co infection in Northeastern Romania. Current data reveal a prevalence of chronic HBV infection of 19.19% in the HIV-infected population, indicating a significantly increased risk compared with the general population.

Our findings highlight the importance of proper management of patients infected with human immunodeficiency virus which has to include prophylaxis, regular screening for HBV infection, and administration of potent anti-HBV therapy in co infected patients according to current guidelines.

CLINICAL FEATURES AND EVOLUTION OF ORGAN DYSFUNCTIONS IN SEPSIS

CLINICAL FEATURES AND EVOLUTION OF ORGAN DYSFUNCTION IN SEPSIS (Abstract): In sepsis, the systemic inflammatory response is adapted to the etiologic agent and the increase in the level of mediators is associated with organ dysfunction. Currently, a rapid assessment of patient ability to develop an adequate immune response is not possible, the response mechanisms being similar in the context of different etiological agents. **Aim:** To find statistical arguments for the evolution of laboratory parameters in sepsis patients. **Material and methods:** This retrospective study included 90 patients diagnosed with sepsis. The clinical, etiological, and laboratory data, and Carmeli and APACHE II prognostic scores were analyzed. The data were processed using SPSS version 16.0. **Results:** The causative agents was identified in 16 cases; organ involvement and systemic response varied, and no statistical correlations were found between the inflammatory syndrome parameters and Carmeli or APACHE II prognostic scores or identification of the causative agent. **Conclusions:** Statistical correlations were found between maximum blood glucose levels and the presence of organ dysfunction in the studied sepsis patients. No correlations were found between sepsis severity and the presence of anemia or thrombocytopenia, or between fever syndrome and inflammatory syndrome. **Keywords***:* DATA ANALYSIS, ORGAN FAILURE, SYSTEMIC INFLAMMATORY RESPONSE SYNDROME.

The notion of sepsis had been under intense debate and considerable efforts have been made over the past 20 years to identify therapies that reduce mortality (1,2). There is such an extraordinary heterogeneity in patients with sepsis characterized by different conditions, infection site, microbial agents with large variations in virulence and concentration, as well as a different inflammatory response and immunological adaptation, that limiting the concept of sepsis to a surge in inflammation may be considered no more than a simplistic approach (3, 4, 5).

Inflammatory response is often adapted to the etiological agent or toxinic aggression or, on the contrary, a series of microorganisms may lead to an increase in the level of mediators that cause aggressions in the infected organism, associating acute respiratory dysfunction, multiple organ dysfunctions, and refractory hypotension (6, 7). At present, a quick evaluation of patients' capacity to show an adequate immune response is impossible and it is considered that mechanisms related to or-

gan dysfunction and those involved in evolution towards death could be similar in the context of different etiological agents, while variable response in sepsis may be related to infection distribution at organ level (7, 8).

MATERIAL AND METHODS

This 7-month retrospective study (January-July, 2013) aimed to determine clinico-epidemiological and evolutive correlations under specific therapy based on the analysis of the data in patient records. Ninety patients with sepsis of known or unknown etiology admitted to the Iasi Hospital of Infectious Diseases were included in this study. The following were analyzed: social status, length of hospital stay, duration of febrile state, etiology, Carmeli prognostic score, APACHE II score, and some biological parameters based on which we tried to establish correlations or differences in terms of statistical significance.

Inclusion criteria were: suspected or proven infection associated with systemic inflammatory response syndrome (at least two criteria: fever/hypothermia, tachycardia/tachypnea, leukocytosis/leucopenia), and severe sepsis diagnosed by the presence of such associated organ dysfunctions as respiratory, renal and cardiac failure, neurologic impairment, disseminated intravascular coagulation or shock.

Biological samples were processed according to the standards for bacteriology, hematology and biochemistry laboratories, and the database created in Excel was processed using SPSS 16.0, $p<0.05$ being considered statistically significant. When quantitative parameters did not show a normal Gauss-Laplace distribution and *t-student* test could not be applied, nonparametric tests were used (*Mann-Whitney Test*).

RESULTS

The 90 patients included in this study were aged 3 to 84 years, mean age 58.5 years, median age 62 years. The mean age of patients associating organ dysfunctions was 60.4 years, while the median age of those classified according to APACHE II score was 59 years. No statistically significant age differences were found between the patients associating organ dysfunction and those without dysfunctions (*calculated* $p = 0.292 > 0.05$).

The causative agents could be identified in 16 cases, and organ and systemic affectation varied (tab. I).

TABLE I

Etiology and organ damage in the study sepsis patients

Microorganism	No. of cases	Isolation site	Organ damage	Carmeli score	APACHE II score
E. coli	4	2 HC 2 HC+UC	kidneys	1 in class 1 2 - 2 1 - 3	2 < 20 (I) 2 between 20-29 (II)

Bacilli Gram negative	1	HC + UC	CNS + liver + kidneys	3	28 (II)
E. coli + Enterococcus spp.	1	HC + UC	kidneys	3	34 (III)

HC= hemoculture; UC= uroculture; CNS= central nervous system

In all study patients the parameters of inflammatory syndrome (white blood cells (WBA), fibrinogen, erythrocyte sedimentation rate (ESR), and CRP were determined upon admission and we aimed at determining both the possible correlations between these parameters and between them and blood glucose levels. Significance level was below 0.05, so no correlations between these parameters were found in our sepsis patients.

Blood glucose levels were higher in patients associating organ dysfunction, the statistically significant difference confirming a correlation between blood glucose level and the presence of organ dysfunction in the study patients (fig. 1).

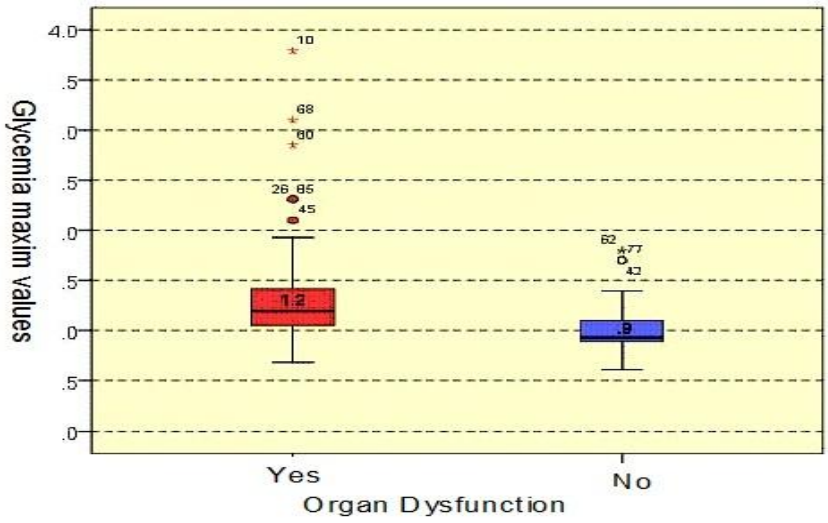

Fig.1. Correlations between blood glucose levels (g/l) and organ dysfunction in the study sepsis patients

DISCUSSION

The statistical analysis of the avriables of systemic inflammatory syndrome has shown no correlations between high blood sugar, fibrinogen, ESR, and CRP levels and high body temperature in sepsis patients with or without associated organ dysfunction.

Anemia syndrome, defined as a serum hemoglobin concentration of less than 10 g%, and thrombocytopenia as a platelet count below 100.000/mm³, were more common in the patients with APACHE II severity classes II and III than class I, but no statistically significant differences were found. Thus, the *t-student* test was used for hemoglobin, and the *Mann-Whitney test* for thrombocytes, the data not being normally distributed.

The possible correlations between organ dysfunction and the identified cause of sepsis were analyzed using the *Chi-Square* test, no statistically significant correlations being found.

CONCLUSIONS

In the study sepsis patients we have found statistical correlations between maximum blood glucose level and the presence of organ dysfunctions.

Anemia and thrombocytopenia, frequently associated with the systemic inflammatory response in these patients, did not correlate with the severity of their sepsis progression. Also, no statistical correlations were found between febrile syndrome and inflammatory syndrome in patients with or without organ dysfunctions.

ENDOSCOPIC THERAPY WITH CURATIVE INTENT FOR NEOPLASTIC EPITHELIAL LESIONS (Abstract): Neoplastic lesions of the gastrointestinal tract have a large prevalence worldwide and in Romania. Their therapy is tailored to their TNM stage, which can be estimated using non invasive or minimally invasive imaging studies. Precursor lesions and superficial carcinomas are amenable to endoscopic therapy, providing that their endoscopic and/or endoscopic ultrasound aspect suggest a maximal extension to the submucosal layer. Polypectomy, endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are ablative techniques used for their curative intent treatment. Large superficial carcinomas are to be removed by ESD as "en bloc" resection is essential to post procedure histological appraisal of the curative oncology nature of their resection. ESD complications rates and duration are nowadays reduced with the aid of "water-jet" technology, by combining submucosal fluid jet injection and electro-resection in a single knife. **Keywords:** ENDOSCOPIC, NEOPLASTIC, "WATER-JET".

NEOPLASTIC EPITHELIAL DIGESTIVE LESIONS

Digestive tract cancers have high prevalence worldwide, colorectal cancer ranking 3rd in all cancers (after breast and lung cancer), gastric cancers ranking 4th and esophageal cancer ranking 8th. In Romania, for 2008, the incidence values are 22.8/100000 for colorectal cancer (2nd in Romania), 10.3/100,000 for gastric cancer (6th) and 2/100,000 for esophageal cancer (20th) (1).

Most digestive tract cancers have epithelial origin, being carcinomas. Transition process from normal epithelium to carcinoma passes through pre-neoplastic lesions with different degrees of dysplasia. Carcinomas invade the digestive wall, from the inner to the outer strata: first are limited to the epithelium (Tis, T0), then invade mucosa and submucosa (T1), next the muscular layer (T2), then the serous membrane (T3) and finally they may invade the adjacent organs (T4), T being the stage in the TNM classification (2).

If a certain level of the wall invasion is reached, neoplastic cells may migrate through the lymphatic vessels to the regional lymph nodes (lymph node metastasis, N1, TNM) or through the blood vessels to distant organs (distant metastasis, M1, TNM). It has been proved that the risk of metastasis is null if the submucosal invasion is less than 200 μm for the esophagus,

500 μm for the stomach and 1000 μm (1mm) for colorectal carcinomas (3,4). There is a direct relation between the T stage and the metastasis risk, with the cut-off between null to positive located at a certain level of the submucosa.

High risk pre-neoplastic and neoplastic lesions are to be treated, if possible, with curative intent by endoscopic or surgical excision, with resection limits in normal tissue. Therapy decision is taken depending on the TNM pre-therapeutic stage, which cannot be precisely known, but only predicted with maximum probability: T stage depending on the endoscopic and endoscopic ultrasound aspect (see forward); N and M stage depending on the endoscopic ultrasound and CT scan aspect and sometimes by other imaging methods (magnetic resonance imaging MRI, position emission tomography PET scan, bone scintigraphy, etc)

Therapy result will only be known after the pathological exam of the resected specimen which will ascertain if the neoplastic tissue has been totally resected with healthy tissue limits.

ENDOSCOPIC THERAPY WITH CURATIVE INTENT

Endoscopic therapy with curative intent aims to excise mucosal and submucosal layer including the neoplastic tissue, with normal lateral and profound resection borders, leaving the muscular layer and serous membrane in place. This can only be achieved for pre-neoplastic lesions and carcinomas staged T0, T1m and T1sm. For these lesions endoscopic therapy is less invasive than surgery.

Post endoscopic therapy pathological exam specimen resection will assess whether the neoplastic tissue has been entirely resected with normal safe lateral and profound limits, as well as the relation between the depth of neoplastic invasion and the metastatic submucosal risk level previously mentioned. If the resection is curative (all neoplastic tissue has been resected, with normal limits, and the depth of invasion is lesser than the metastatic submucosal risk level) then no complimentary therapy is necessary. Otherwise, if the resection is not curative, a complementary treatment is needed, endoscopic or more often surgical. This histological assessment can only be done is the lesion has been resected in a single specimen.

PRE-ENDOSCOPIC THERAPY STAGING

Pre-neoplastic and neoplastic lesions with invasion limited to mucosa or submucosa (T0, T1m or T1sm) are considered "superficial" neoplasm, type 0 in the Japanese classification of digestive tract carcinomas (5). These lesions can be further subdivided according to Paris classification in polypoid and non-polypoid (3,4), each subtype having a certain risk of submucosal invasion (tab I).

Moreover, for colorectal lesions, the submucosal invasion risk can be estimated depending on the shape of the mucosal crypts at high resolution endoscopy, the "pit-pattern" analysis defined by Kudo (6,7). Type I (*round*) and type II (*stellar*) pertain to non-neoplastic lesions (hyperplastic polyps), type III_S (*short tubular*), type III_L (*long tubular*) and type IV (*branched*) correspond mainly to adenomas or at most Tis carcinomas, while type V (*irregular and non-structured*) corresponds to carcinomas, frequently invasive into submucosa. The submucosal invasion probability is 4% for type III_S, 0% for type IV and 41% for type V.

TABLE I

The risk of submucosal invasion for superficial carcinomas (type 0 in Japanese classification) according to their endoscopic aspect in Paris classification

Type	Subtype		Esophagus	Stomach	Colorectal
Polypoid	0-I		79%	57%	
	0-Ip	Pedunculated			5%
	0-Is	Sessile			34%
Nonpolypoid	0-IIa	Superficial, elevated	48%	29%	4%
	0-IIb	Superficial, flat	15%	20%	0%
	0-IIc	Superficial, depressed	27%	40%	61%
	0-III	Excavated	84%	-	-

The accuracy of endoscopic ultrasound in superficial carcinoma staging is 69-76% for esophageal lesions (8, 9, 10), 86% for gastric lesions (11) and 60-80% for colorectal location (12).

CURATIVE INTENT ENDOSCOPIC RESECTION AND METHODS

Classical indications are pre-neoplastic lesions and superficial carcinomas staged uT0 or uT1m in endoscopic ultrasound with an endoscopic aspect suggesting submucosal invasion absence.

To these, extended indications add carcinomas staged uT1sm in endoscopic ultrasound and carcinomas with possible submucosal invasion. The explanation for these extended indications lays on 2 factors: *first*, the frequent over-staging by endoscopic ultrasound of these lesions and *second*, on the fact that even if there is submucosal invasion, the resection may still be curative if the metastatic submucosal risk level has not been reached.

In all cases, but especially for extended indications, the post resection histological assessment is essential, which makes the *"en bloc"* resection imperative.

The polypoid pedunculated (0-Ip) lesions are resected by polypectomy, while the polypoid sessile (0-Is) and non-polypoid lesions are resected by endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD).

For superficial gastric cancer, in tab.II are mentioned the classical and extended indications for EMR/ESD and surgery, as formulated by the *Japanese Gastric Cancer Association*, by Gotoda (13, 14). To note that besides the endoscopic aspect, the size and differentiation are factors to be taken into account when establishing the therapeutic method.

EMR versus ESD

EMR and ESD use fluid injection into the submucosa to make lesions became protrusive and distance them from the *muscularis propria* so as to avoid its thermal injury with consequent perforation. While for EMR the lifted lesion is resected in one or multiple fragments (in case of large lesions) by the polypectomy snare, for ESD the lesion is dissected around and beneath in the submucosal space, in a similar fashion to surgical dissection, thus obtaining a one piece resection specimen.

TABLE II

Therapeutic indications for superficial gastric carcinomas. ❖– classical indication for EMR. ☒– extended indication for ESD. ⛆– relative indication for surgery. ★– absolute indication for surgery.

Histology	T1m carcinoma				T1sm carcinoma	
	Non ulcerated (0-IIa, 0-IIb)		Ulcerated (0-IIc, 0-III)		Sm1	Sm2
	≤20mm	>20	≤30	>30	≤30	Any size
G1, G2, differentiated	❖	☒	☒	★	☒	★
G3, undifferentiated	⛆	★	★	★	★	★

The ESD technique is as follows: marking of the lesion using coagulation dots around the lesion is firstly done, next fluid is injected into the submucosa beneath the lesion so as to lift it, then a circumferential incision around the dots is performed and finally the submucosal space under the lesion is carefully dissected. Dissection is done using specially designed knifes (fig. 1). The procedure is usually long, needs repeated fluid injection and preventive or therapeutic hemostasis of submucosal vessels.

(a) (b) (c)

Fig. 1. ESD knifes. (a) Dual knife, (b) Hook knife, (c) IT Knife 2

ESD has emerged as an alternative to multiple fragments "piece-meal" EMR, the advantages of ESD being:

- it respects the principles of surgical oncology - a one piece resected specimen allowing for histological assessment of its curative or non-curative nature. If lateral and profound borders are clear of the disease and there is no risk of distant metastasis the resection is curative. If the borders are not clear of the disease or the invasion depth is deeper then the submucosal metastasis risk level, then the resection is not curative and a complementary therapy is needed;
- the local relapse rate is minimal because there is theoretically no residual tissue;

In the mean time, ESD has some potential disadvantages:

- the bleeding and perforation risk is higher than for EMR. In a French ESD

register published in France in 2011, on the 118 cases realized in more than 2 years, the bleeding rate was 11.2%, while the perforation rate was 18.1%. The complications rate was 18.5% for the esophagus, 24% for the stomach and 36.5% for colon and rectum (15)

- a longer procedure time, which can reach several hours for lesions sized 10 to 15 cm diameter.

"WATER-JET" TECHNOLOGY IN EDS

Many ESD knifes have been designed to lessen its disadvantages. Some late generation knifes have multiple capabilities, both for submucosal dissection and fluid injection. The aim is to lower perforation rates and shorten procedure time.

The simplest of such knife is Flush Knife developed by Fuji Corporation (fig. 2). Apart its dissection role, it also has fluid injection capability, but only for washing the operating field during procedure improving visibility, and not for submucosal elevation. This knife has already entered in endoscopy practice, with very good results in clinical trials – one case series with 100% "en bloc' resection rate, no complications and no local 12 months relapse rate (18).

The second knife with mixed capabilities has been developed by the ERBE Corporation, the Hybrid Knife (fig. 3). It allows both submucosal injection and dissection, shortening the procedure time by avoiding the frequent instrument exchange in the operating channel during the procedure (dissection knife and injection needle). Consequently, the perforation risk is minimized because the operator may inject fluid into the submucosa at any time during procedure, keeping the muscular layer at distance and avoiding its thermal injury. It has been initially developed for neurosurgical interventions (19). Initial in vivo animal studies have shown good results: it lowers complications rates on esophageal ESD (20), it decreases complications rate and procedure time in the stomach (21) and it diminishes perforation rate for colorectal ESD (22).

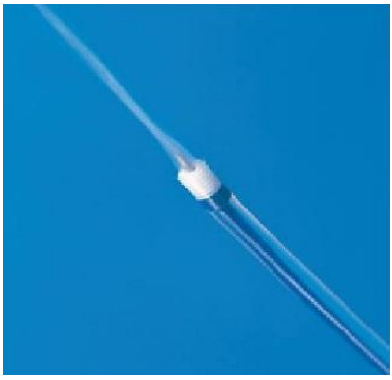

Fig. 2. Flush Knife.

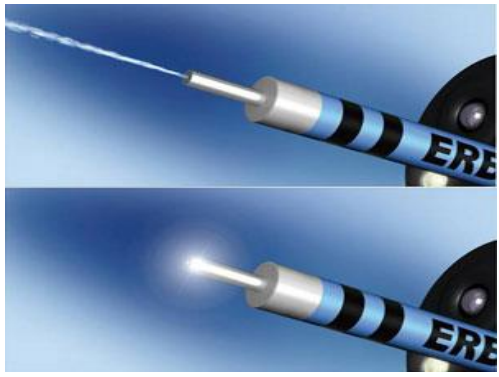

Fig. 3. Hybrid Knife

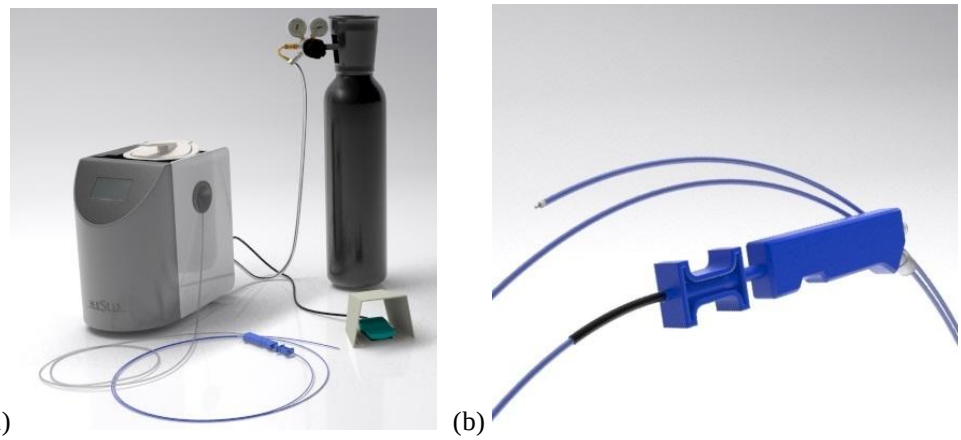
The two abovementioned instruments are already in clinical practice; in the French paper previously mentioned 16% and 12.8% of the ESD procedures have used Flush Knife and Hybrid Knife respectively (15).

The last mixed knife capability is ENKI-2 developed by NESTIS Corporation (fig. 4). The principle of a single submucosal dissection and injection instrument is kept, as for Hybrid Knife, but the difference is in the way of achieving fluid injection pressure: for Hybrid Knife an electrically driven fluid pump is used, while for ENKI-2 the injected fluid lays in a liquid nitrogen pressure chamber. The difference in fluid injection is significant, because high pressures are obtained with a constant pressure during injection, without an ascending and descending phase (fig. 5).



(a) (b)

Fig. 4. ENKI-2 system. (a) ENKI-e dissection knife connected to the pressure chamber, itself connected to a liquid nitrogen canister; (b) details of the EKNI-2 knife

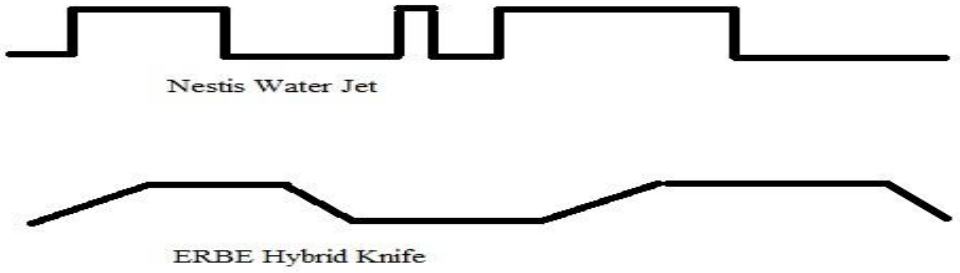


Fig. 5. Fluid injection pressure variation, comparison between Hybrid jet and ENKI-2

OUR EXPERIENCE

We have been part of the team testing the ENKI-2 system in vivo animal models. The results show that ENKI-2 fluid injection increases dissection speed of gastric ESD, but it will not be faster than knife electro-dissection, even with a pulsed injection pattern (25). ENKI-2 diminishes the perforation rate and the procedure time for an experienced ESD operator, while for an inexperienced one the decrease is not statistically significant (26). Here are some images from these in vivo experiments on colorectal pig model, from our collection (fig. 6).

ENKI-2 has CE marking; it is already used for human cases and is available in many centers throughout Europe.

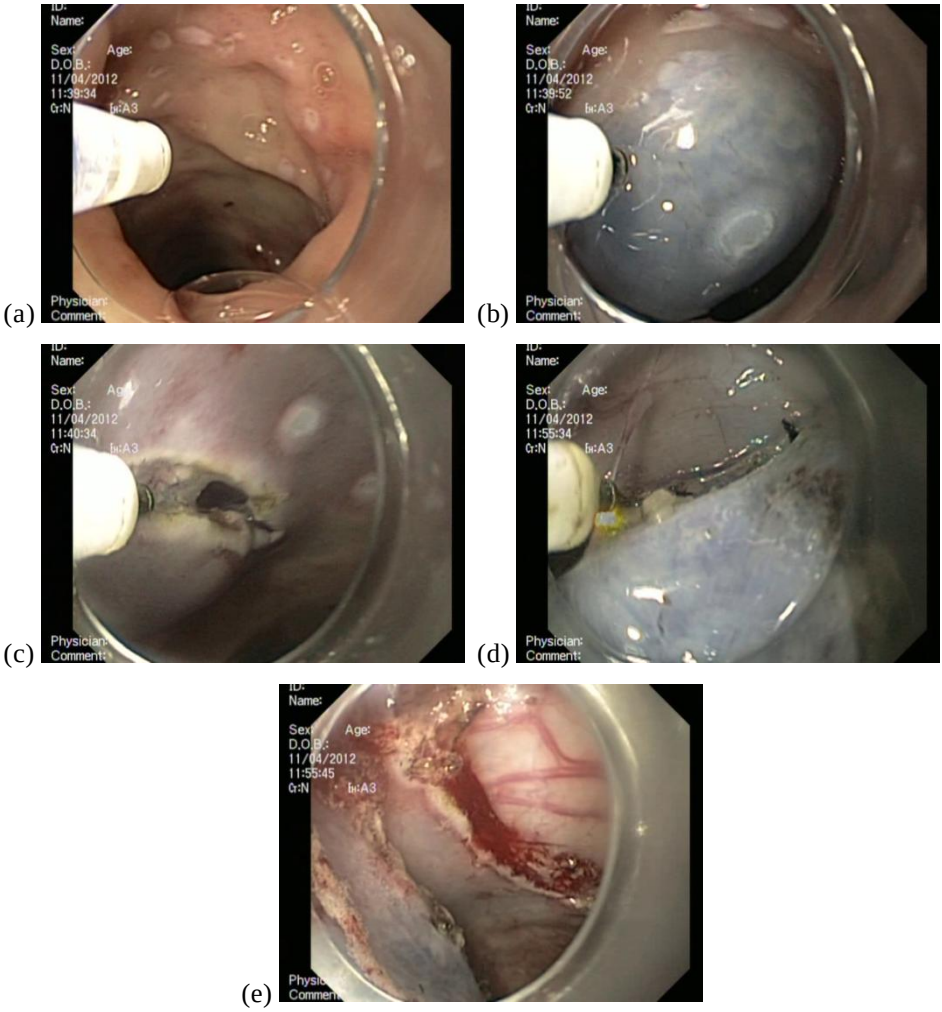

Fig. 6. ESD using ENKI-2 in pig colon and rectum, in vivo (our collection). (a) an artificial 30mm diameter lesion is delineated using coagulation dots on the pig's colon and rectum mucosa; (b) high pressure fluid injection with epinephrine and indigo carmine(c) circumferential incision; (d) submucosal dissection with preventive hemostasis on submucosal vessels; (e) the post resection ulcer borders at the end of the procedure

In conclusion, endoscopic resection of pre-neoplastic and neoplastic superficial lesions may be done endoscopically by ESD, respecting the principles of surgical oncology and "water-jet" technology may facilitate this procedure.

AUTISM, AN OVERWHELMING CONDITION: HISTORY, ETIOPATHOGENESIS, TYPES, DIAGNOSIS, THERAPY AND PROGNOSIS

Ioana Cristina Amihăesei, Elena Ştefanachi
University of Medicine and Pharmacy "Grigore T. Popa" - Iaşi
Faculty of Medicine
Discipline of Histology

AUTISM, AN OVERWHELMING CONDITION: HISTORY, ETIOPATHOGENESIS, TYPES, DIAGNOSIS, THERAPY AND PROGNOSIS (Abstract): Autism is defined as a neurologic developmental disorder affecting brain and behavior, becoming usually apparent before 3 years of age, with stable evolution and no remission. No neurologic morphologic abnormality was associated with the disease. Several types of disease being described, autism is part of a larger spectrum known as autism spectrum disorders (ASD), or pervasive developmental disorders (PDD). The disease was first described long before it was defined and it has received its modern name. Main cause in the development of autism is considered to be genetic, up to 90 %. However, environmental factors could be incriminated, sometimes. The five types included in ASD are: Asperger syndrome, pervasive developmental disorder-not otherwise specified (PDD-NOS), typical autism, Rett syndrome and childhood disintegrative disorder (CDD). The classical triad of symptoms includes: social interaction impairments, communication impairments and repetitive, stereotype behavior. Diagnosis is based on interview of the parents and specialized observation of the suspected children. Main tools used in therapy are the family and the educational system. Well established, specialized programs of therapy were developed in time. Prognosis of autism is severe, since no cure is possible; nevertheless spontaneous recoveries do occur, in some cases. **Key words**: AUTISM, AUTISM SPECTRUM DISORDERS (ASD), PERVASIVE DEVELOPMENT DISORDERS (PDD)

Some cases were described long before the disease has received its name and its characteristics were established. The earliest well-argumented case of autism is that of Hugh Blair of Borgue, which is described in a law report from 1747, where his brother tried to revoke Blair's marriage, in order to obtain the inheritance.

The Swiss psychiatrist Eugen Bleuler first used the word autism (from Latin, autismus) to describe symptoms of schizophrenia. In fact, the word is deriving from the Greek *autós* (self) and was used to define abnormal self-admiration and autistic isolation of the patients in their fantasies, in which outside influence became intolerable (1).

In 1938, Hans Asperger of the Vienna University Hospital used the term autistic psychopaths in a lecture, thus the term autism found its modern sense. Asperger then described the entity now known as the Asperger syndrome, although the condition was not recognized as a separate diagnosis

till 1981.

In its modern sense, in English language, the term autism was first used by Leo Kanner (Johns Hopkins Hospital), when he reffered in 1943, to „early infantile autism"; he was then describing 11 cases of autism. His description was so accurate that is still typical for the autism spectrum disorders (2).

In the late 1960s, autism was recognized as a syndrome with life-long duration, distinct from other development disorders, such as mental retardation or schizophrenia; it was also widely accepted the benefit brought up by the active therapy programs. Although in 1970, the genetic etiology of the autism it was still not clear, now the disease is considered one of the most heritable of all psychiatric diagnoses (3).

ETIOPATHOGENESIS

The genetics of autism is complex and is not yet clear if autism can be explained by genetic mutations, or by peculiar multigene interactions of common genetic subtypes. Its complex features develop from interactions between multigene, environment and factors which are able to influence the gene expressions. Genetic factors are estimated to represent over 90 %, in the genesis of autism. Studies on twins have shown that many of the non-autistic siblings do manifest however, social and/or learning disabilities (4).

The risk of hereditary transmission in the families with autistic individuals was estimated at about 30 %. Linkage and association genetic analyses were unconclusive. It seems that more than one gene is involved; more such genes were located, but the specific mutations could not be identified. Recently was accepted that several different causes might finally lead to autism, as it is the case with the mental retardation, when different types of brain abnormalities would have the same final result (5,6).

The number of autism diagnoses increased dramatically, especially after 1980, and even more in 1990 and 2000. It seems that this is due, at least in part, to modification of the diagnosis procedures. It is not yet established if the prevalence of the disease increased in the same measure (2008 – 11.3 children/1000, 2012 – 20 children/1000, in U.S.A) (7).

Environmental factors may rather aggravate than trigger, the development and the evolution of the disease. Among such factors, considered to be involved are: infectious diseases, solvents, heavy metals, phtalates and phenols from plastic products, drugs, pesticides and vaccines (8).

In a certain way, autism seems to be directly opposite to schizophrenia, since in autism are expressed paternal genes which are regulating the overgrowth of the brain, while in schizophrenia are expressed maternal genes, which are inducing the underdevelopment of the brain (9).

Advanced paternal and maternal age at the time of the procreation are also incriminated in the genesis of the autism. From the point of view of the paternal age, two theories are suggested: mutations accumulated in time, which would affect the quality of the spermatozoa, and the autistic traits of personality, which would determine such male individuals to marry and procreate later; the two hypotheses are in fact completing each other. It is difficult to appreciate to what extent, paternal or maternal age, or both are important in the genesis of the disease (8).

Prenatal viral infections which are clearly involved are rubeolic and cytomeg-

alic virus infections. The rubeolic congenital syndrome is the most striking proof of the involvement of non-genetic factors in the genesis of the autism. Teratogens, such as thalidomide, valproic acid/misoprostol are involved as well, in the development of the disease. The alcoholic fetal syndrome is also increasing the risk for autism.

The gestational diabetes was found as a significant risk factor, in a 2009 study, demonstrating a risk for having an ASD child, two times higher than in the case of the non-diabetic mothers. In a study conducted in april 2012, metabolic syndrome, associating diabetes, obesity and high blood pressure was more frequent among mothers of ASD children; in the same study, the interrelation between obesity and pregnancy, as a single risk factor for having children with autism was also found strongly positive (7,8).

The opiate theory was advanced in 1979 by Jaak Panksepp, who noticed that small amounts of opiate substances injected in young laboratory animals, produced symptoms similar to those found in autism. He postulated that a digestive abnormality present at birth, could lead to the transformation of the gluten and of the caseine into opiate substances – gliadorphine and caseomorphine, which would interfere with the capacity of sensory reception in these children. Thus, they will show a need for constant stimulation, at the visual level (obsession for rotating objects, characteristic movement of the fingers in front of the eyes, etc.), auditory level (screaming), vestibulary level (swinging, spining, rotatory movements) and tactile level (hand clapping, self-injury) etc., which would explain at least partially, the symptoms of autism. Yet, the scientific data are not validated to exclude these type of nutrients from diet (10, 11).

Another factor incriminated in the development of autism is the prenatal exposure to important stress. The theory of the fetal testosterone is stating that the increased levels of testosterone in the amniotic fluid would force the brain development toward an increase in the complex analysing and synthetic capacities, in the detriment of the communication abilities and empathy (an overdevelopment of the so-called „male traits" and a decrease of the „female traits" of personality); the theory was controversial and contradicted by other studies. Other perinatal incriminated factors are: the small birth weight, the gestational age and hypoxia at birth. Vaccines were incriminated, especially because numerous parents became aware of the autistic symptoms of their children, concomitantly with a routine vaccination. An impressing number of well-validated studies have infirmed this wrong belief (12, 13).

Pathophysiology is supporting the influence of the amygdala neurons which are involved in the development of the social skills and in the capacity to learn social behavior patterns, and the involvement of the noradrenergic system of the loccus ceruleus, a neuronal system known to be involved in excitation and attention, and thus influencing the learning abilities and the capacity to adapt to the environment. The pathophysiologic theories are involving the cortical structures and their interrelation with behavior (14).

The overdevelopment of the brain of the autistic subjects early after birth would be responsible for an increased number of neurons, an overdevelopment of the synapses in certain key cortical zones, an unbalanced functioning of the neuronal excitatory, versus inhibitory networks. The ab-

normal development of brain synapses is involved as well in the genesis of the epilepsy, thus explaining the frequent association between the two conditions (15).

The theory concerning the mirror neuronal system: this system is activated when a laboratory animal is achieving a task, or is observing another animal achieving the same task. This system would be involved in the capacity of imitating activities, intentions and emotions, through the observation of other individuals. The abnormal development of the mirror neuronal system would interfere with the capacity of imitation, which is important in creating behavioral patterns. The delay in the activation of the mirror neurons was noticed in the Asperger syndrome (16).

A reduced functioning of the deficit neuronal network was also incriminated in the pathogenesis of autism; this network is involved in social and emotional processing, and consequently, in attention and concentration abilities. It has extended connections with the excitatory neuronal networks and it seems that in autism the two networks are not efficiently interconnected, with a deficit in the capacity to rapidly change one circuit, for the other; this could be responsible for a disorder in the capacity of thinking about the self. In ASD individuals was evidentiated a peculiar type of signals in the cingulated cortex, in an imagistic study from 2008. The theory of the reduced interconnections is presuming the presence in autism of an overdevelopment of the neuronal interconnections, but which are underfunctioning and with a syncronization deficit, with an excess of low-level processing. In autism are present reduced functional connections between the frontal lobe and other cortical areas. Imaging studies and brainwave studies which have analyzed cortical reactions according to the events the subject had been exposed at, showed the preference of ASD subjects for the non- social stimuli (17).

TYPES

Autism spectrum disorders are including five types of autistic developmental disorders.

Asperger syndrome is the most frequent and fortunately the least severe form of autism. It is characterized by disabilities of social interaction and communication. Usually, the subjects do not accept changes in the daily routine and they show a form of learning disability. Motor skills of these subjects are underdeveloped and they are clumsy: they show usually a hypersensitivity for powerful visual and auditory stimuli. Frequently such subjects are intelligent, with high IQ scores, and they may demonstrate a peculiar talent in a domain, in which they are unusually gifted. They have the habit to learn everything about a single subject in which they became obsessively interested, and afterwards they spoke continuously only about this subject. Sometimes, Asperger syndrome and high functional autism are superposed, although this is not clear established by the specialists. Adults with the diagnosis of Asperger syndrome are at higher risk for the development of anxiety and depression (18).

Pervasive Developmental Disorder not otherwise specified (PDD-NOS). The large majority of the ASD cases are receiving this diagnosis. Usually, these subjects show autistic symptoms more severe than the Asperger syndrome, but they do not meet entirely the diagnosis criteria for typical autism. In such cases the diagnosis is that of PDD-NOS. These patients show im-

pairment of the social function, language abilities better developed than in the typical autism, but not so good as in Asperger syndrome and fewer repetitive behaviors, than in the Asperger syndrome, or typical autism. The disease usually has a later age of development (19).

Typical autism is characterized by clear diagnosis criteria; social function and language abilities are severely impaired and repetitive behaviors are characteristic. Such cases frequently associate mental retardation and convulsive symptoms.

Rett syndrome is affecting almost exclusively the female sex; it is very rare – 1/10-15,000 children. Usually at an age between 6 months and one year and a half, the child cease to respond to social stimuli, a characteristic hand grasping reflex is appearing and the language abilities are rapidly lost. Motor coordination problems may sometimes evolve severely. The syndrome is the result of a single gene mutation, which is not inherited, but the result of the hazard (20).

The childhood disintegrative disorder (CDD) is the most severe form of the autism spectrum disorders, fortunately also the rarest of all. After a period of normal development, usually between 2 and 4 years of age, such children are rapidly losing social, intellectual and language abilities. Frequently, a convulsive disorder is associated and the severe symptoms cannot be recovered. Male sex is more often affected; less than 2 children/100,000 affected by autism spectrum disorders are developing this syndrome (19, 20).

DIAGNOSIS

The diagnosis of autism is based upon the classical triad of symptoms: social development impairment, communication disabilities and the repetitive, stereotype behavior. Other symptoms, such as atypical alimentation are frequent as well, but are not essential for the diagnosis.

It is important to stress, the fact that the common symptoms of ASD are present in the general population, wthout frequent association, and there is no clear border to separate the severe pathology and the ordinary personality traits (21).

The social function impairment is the most striking characteristic of the disease, distinguishing it from other syndromes. These children are smiling and are looking at others more rarely, when they are called by their name. A striking characteristic is that they establish much more rarely visual contact with the others. At 3-5 years of age, they show a poor understanding of the social activities and a reduced capacity to spontaneously contact other people, to imitate, to respond emotionally and to infer the emotional estate of other people.

Communication impairment is affecting 1/3, up to ½ of the autism cases, in such a degree that these subjects do not develop communication skills enough to satisfy their usual needs. In the first year of life delayed babbling, unusual gestures and vocal manifestations are common. They ask more rare different things, they manifest echolalia and the capacity to point or to indicate something, in order to communicate is constantly affected. Autistic subjects show impairment of the complex, abstract and deductive language, proved by poor results at such tests.

The repetitive behavior is classified under The Repetitive Behavior Revised Scale of 2007: stereotype movements (hands flapping, body swinging etc.), compulsive behavior is following rigid rules (such as the arrangement of different objects in precise

position); resistance to change, ritual behavior, restrictive behavior (obsession for one game, one toy or one TV program etc.); self-injury is reported to affect approximately 30 % of the autistic children (22).

Other symptoms are including sensory abnormalities (more often hypo reactivity), motor impairment (in coordination, reduced muscular tonus), alimentary behavior abnormality (affect up to ¾ of the cases, for that it was once used as a diagnosis criterion; selectivity is the most frequent problem, but ritual at table and food refusal are also common).

Imagistic techniques, MRI and diffusion tensor imaging are used to identify characteristic features for autism, visible on brain scanning.

Important clues for the diagnosis are:

- no babbling till 12 months
- no gesture till 12 months (like to point with a finger)
- no word till 16 months
- no two words proposition (spoken spontaneously and not echolalia) till 24 months
- any regress in what concerns social or language skills, at any age of the child

Diagnosis standards impose at least 6 symptoms, including at least two symptoms of the quality of social interaction, at least one symptom of language disability and at least one of repetitive and restrictive behavior.

Diagnosis instruments that are frequently used are: the Autism Diagnosis Interview Revised, which is a partially structured parent interview and the Autism Diagnosis Observation Schedule, which uses observation and interaction with the child. The Childhood Autism Rating Scale is used in specialized clinic environment, to evaluate the severity of autism through children observation (23).

Differential diagnosis includes the mental retardation, auditory problems, language impairment syndromes, as the Landau-Kleffner syndrome, which can be diagnosed on EEG.

Although an early diagnosis is important for the initiation of the therapy and good chances of recovery, unfortunately this is rarely done in practice (25).

A 2009 American study showed that the ASD diagnosis was established at an average age of 5.7 years, which is far below the recommendations (5). There are cases not diagnosed till adult age, and also cases that are over diagnosed based on uncertain symptoms (21).

Frequently associated co-morbidities are: mental retardation (reports are ranging from 25 to 70 %, a large variation reflecting the difficulty of a correct evaluation of the intelligence of the autistic individuals); anxiety is common among autism spectrum disorder subjects, there are studies which report a frequency of up to 84 % of the autism cases; epilepsy, metabolic syndromes (phenylketonuria), ADHD (attention deficit and hyperactivity disorder) Tourette syndrome are also commonly associated in the ASD patients. Sleep troubles are affecting approximately 2/3 of the autistic patients, representing a reason for initiation of therapy, besides the autism symptoms (23, 24, 25).

THERAPY

Main goals of the therapy of autism are to diminish the deficits associated with the disease, and to relief the stress endured by the family, as well as the increase of the life quality and the degree of autonomy of the patients.

A standard therapy does not exist, the

treatment is addressed strictly to the needs of the respective child. Main resources used in the therapy are the family and the educational system. Studies which tried to evaluate the efficiency of different therapeutically methods were inconclusive; however, the psychosocial methods used do show positive effects, suggesting that whatever form of therapy is preferable than none. The applied therapies are improving the adaptive capacity and are decreasing the severity of the symptoms and of the behavior troubles. Most used methods are: the Applied Behavior Analysis (ABA), developmental models, structured learning techniques, speech therapies, social functions therapy and occupational therapy (26).

The opportunity of including ASD subjects with different degrees of severity in the mass educational system is still debated. Many types of medications are used; most frequent antidepressants, stimulatory drugs / psychotropes and antipsychotics. Besides antipsychotics, there are few studies to support the safety of the use of such medications, in autism. The risk of atypical reactions and the high risk of development of side effects are difficult to estimate, in the case of autistic individuals. Till this moment, there is no known drug capable to cure or to diminish the symptoms of autism (27, 28).

In time, numerous unconventional therapies were used in the treatment of autism, such as: acupuncture, antifungal therapy, art therapy, the Denver model, therapy using dolphins, aerobics (interactive computer programs), facilitated communication, music, contact therapy, homeopathy, neuro-feedback, rhythms therapy, yoga etc (19).

PROGNOSIS

Autism is not curable; spontaneous recoveries may occur, revoking the autism diagnosis. The recovery may appear sometimes after intensive therapy, but not always. The reported rates of recovery in U.S.A. are situated between 3 and 25 % of the total number of cases. Most autistic children do learn to speak around 5 years of age, some earlier, but some later.

Most ASD adults tend to manifest milder symptoms, than during childhood. Studies to evaluate the evolution of the ASD subjects, above medium age do not exist.

Usually, learning to speak before age of six and an IQ score above 50 are meaning a better future potential.

Different studies show that a high level of autonomy was reached in 4-12 % of the cases. At the opposite pole, 12 % needed hospitalized specialized care, all lifelong. The large majority (46 %) needed continuously specialized residence and achieved only limited autonomy (20).

The costs of autism are very important; in U.S.A., a child born in 2000, needs for his life-duration 3.99 million dollars (adjusted according to the inflation rate for 2013) (7, 29).

COXARTHROSIS – DISEASE OF MULTIFACTORIAL ETIOLOGY. METHODS OF PREVENTION AND TREATMENT. THE ROLE OF KINESITHERAPY IN COXARTHROSIS (Abstract): Coxarthrosis is a disorder of the physiological balance between the strength of the articular cartilage and articular bone, and between the pressures exerted on the joint. It is a disease with a slow progressive and long course. Its insidious onset and progression, marked by variable periods of stagnation lasting months or even years make it difficult to establish the time of onset. **Material and Methods**: The study was conducted between January 2012 and December 2012, on a series of 27 coxarthrosis patients, diagnosed at the Rheumatology Clinic of the Iasi Rehabilitation Hospital. **Results and Discussion**: Of the 27 patients, 11 (40.74%) had primary bilateral coxarthrosis, 8 (29.63%) early coxarthrosis, right, 6 (22.22%) coxarthrosis, left, secondary to aseptic femoral head osteonecrosis, and 2 (7.41%) patients had bilateral coxarthrosis secondary to acetabular insufficiency. Kinesitherapy proved to be highly effective in the rehabilitation of coxarthrosis patients by alleviating pain, mechanical protection of the hip joint, walking rehabilitation in total hip arthroplasty, and social and professional integration of the patients. The massage besides its analgesic effect also acted as a muscle relaxant. Once the objectives have been met, the kinesiology program becomes global and functional rather than analytical, as it aims at reintegrating the coxofemoral joint into normal movement patterns. **Conclusions**: Kinesitherapy has been shown to be a physical treatment that can not be replaced by other rehabilitation methods and is crucial in the recovery of lost functions. **Keywords**: COXARTHROSIS, KINESIOTHERAPY, REHABILITATION.

One of the main characteristics of living matter is movement. Throughout its long evolution, movement has continuously improved. It has gradually evolved from the simplest movement of unicellular organisms to the movement performed by a specialized apparatus, namely the locomotor system in animals (1).

The coxofemoral joint (Fig. 1) can be compared with a mechanical system that from an anatomical point of view displays three degrees of freedom of motion: *flexion-extension* (along the sagittal plane), *adduction and abduction* (the lower limb moves away respectively toward the other limb, in the frontal plane of the body,

around the anteroposterior axis); *internal and external rotation* (performed horizontally around a vertical axis) (Fig. 2).

The coxofemoral joint is of great importance for the static position (in unipodal and bipodal support that distributes weight from the pelvis to the lower limbs) and for the locomotion (it provides the swing of the lower limb during the swing phase) (2). Hip stability is due to bone factors, providing vertical stability, ligament factors, providing anterior stability, and muscle factors, particularly influencing anterior stability (3,4).

Fig. 1. Coxarthrosis

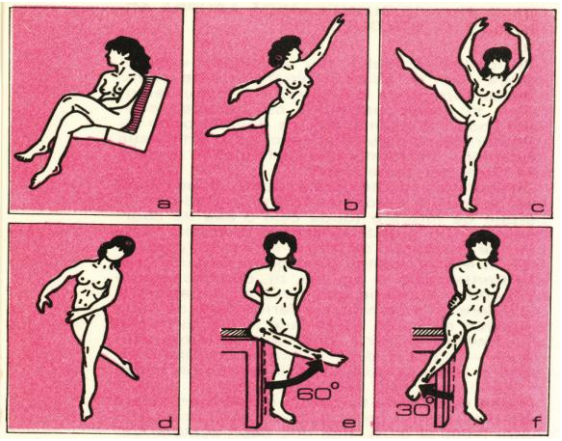

Fig. 2 The coxofemoral joint can be seen as a cardanic articulation

Typical to the physiology of joint movement is a quite low friction coefficient (between 0.005 and 0.01). The pressure regime also varies and the movement is sometimes made under the high pressure of body weight and sometimes just under the lower pressure of muscle contraction (4). Such a small friction coefficient is due to the extremely low roughness of joint surfaces, and the viscosity of the synovial fluid varies inversely with the speed of joint movement (5). The type of synovial lubrication changes depending on the exerted pressure and the speed with which the movement is made.

The biomechanical approach of the locomotor system allows a deeper understanding of how the premature joint wear occurs and develops and, in case of the hip, how coxarthrosis evolves (5, 6).

Just like any other joint, the hip is always under the influence of the permanent static pressure generated by the contraction of different muscle groups. In addition, there is an intermittent dynamic pressure caused by body weight during standing and walking. The circumstances under which the hip joint acts in the unipodal stance justify why a force four times one's body weight is exerted on the articular surface. In order to maintain the equilibrium of the basin towards the femoral head, the action of body weight must be counterbalanced by muscle strength. As the muscle force lever arm is three times lower than that of body weight, a resultant force with a value about four times that of body weight measured above the hip is exerted on the hip. This

force is evenly distributed over the entire articular surface (6).

This congenital or acquired deficiency, more or less pronounced, that affects the supportive joint tissues, can lead to an imbalance (secondary coxarthrosis) (7). An abnormal increase in articular pressures caused by the decrease in the contact area between the articular surfaces leads to the disruption of the normal balance (primary coxarthrosis).

If the pressure exerted on the joints exceeds the resilience of supportive tissue, a series of pathological changes occur that induce major changes in joint configuration during the development of coxarthrosis.

Genes that are involved in most topographical variations of arthritis are most probably those coding vitamin D receptors. They influence bone mass, the proximity of loci for type II collagen, a major component of hyaline cartilage, the insulin-like growth factors 1, the cartilage oligomeric proteins, and the human leukocyte antigen (HLA) system (8). It has been suggested that the disease loci could be placed on chromosome 2q and / or 11q. There is evidence that the different locations of arthritis are genetically encoded in distinct loci.

In the early stages, the number and activity of chondrocytes increases, followed by their progressive decrease. The synthesis of proteoglycan (PG) in chondrocytes decreases and the amount of lytic enzymes and matrix metallo-proteinases (MMP) increases (9). Their production is stimulated by pro-inflammatory cytokines (IL-1, IL-6, TNF-α) and by mechanical factors. Moreover, plasminogen activates latent MMPs. Tissue inhibitors of metalloproteinases (TIMPs) and plasminogen activator inhibitor-1 (PAI-1) has an inhibitory effect on MMPs and plasminogen, respectively.

The arthritic damage progresses under the influence of proinflammatory and proteolytic biological systems, of which the most important are IL-1 (active mediator of inflammation, with a major role in tissue destruction), PG, nitric oxide (NO) (the latter stimulates the production of proinflammatory cytokines - especially IL-1 and TNF-α - and induces vasodilatation and increased permeability) and MMPs.

Diagnosis and clinical management. The diagnosis of coxarthrosis is facilitated by history taking that may reveal the onset of the disease, its location, the rhythm and radiation of pain. Coxarthrosis has two fundamental aspects: increased mechanical stress on joints (excessive loading, congenital or acquired defects of body architecture) and alteration of cartilaginous tissue, leading to the development of osteoarthritis. The secondary cartilage changes are due to metabolic, infectious or inflammatory factors. The disease manifests itself by the gradual and progressive occurrence of pain in the hip, a mechanical type of pain that occurs in motion and relieves itself or disappears at rest.

In most cases, pain occurs in the groin and radiates to the anterior side of the thigh and further to the knee. In other cases, pain occurs in the buttock area. At the disease onset, pain is triggered by position changes and in the more advanced forms of disease pain becomes permanent. Pain arises from small efforts, is more difficult to alleviate and requires a longer resting period. Later, pain occurs at the first steps, but it disappears when the joint warms up and it reappears if the effort is prolonged (10). Pain becomes more frequent over time and it is associated with limitation of joint mobility. As pain worsens and the limitation of joint

mobility occurs, lameness becomes permanent and pronounced, progressively reducing the functionality of coxarthrosis patient. Bone crepitus reported by patients and revealed by the clinical examination indicates the severity of the bone lesion.

Diagnosis should be made at an early stage of the disease so that treatment to be as effective as possible. Short term joint stiffness (<30 min) occurs as a result of the thickening of the synovial membrane and articular capsule (11). The limitation of joint mobility is a consequence of the retraction of the articular capsule, of the osteophytes and of the incongruence of the articular surfaces. Joint instability occurs as a result of weakening periarticular muscle strength and deformities of the bone ends that make up the joint.

The radiologic examination is the preferred method for diagnosing coxarthrosis and assessing the femoral head shape, the appearance of the joint space, the presence of osteophytes and changes in femoral head structure.

A new type of radiographic procedure, a technical version called micro focal radiography, with high spatial resolution, can detect early changes invisible to standard techniques.

Scintigraphy with methylene or hydroximethylene diphosphonate shows details about blood flow in the bone and soft tissue and bone turnover. Ultrasound can assess the arthritic process and the degenerative changes. Lesions that remain invisible on radiographs are identified by the high sensitivity and specificity of nuclear magnetic resonance imaging.

Therapeutic guidelines. Coxarthrosis treatment aims at decreasing pain intensity and increasing stability, mobility, coordination and balance during walking.

Currently, the therapeutic regimen for patients with coxarthrosis is a long term process that takes place in two stages: a medical conservative stage that combines a program of joint hygiene, with drug therapy (analgesics and chondroprotective agents) and kinetic physical therapy, which is a maintenance therapy or a functional rehabilitation (12) and a surgical stage.

Treatment aims to reduce pain and the functional discomfort of the patient and at the same time to stop the development of joint damage. Conservative treatment is effective in less advanced forms. Pain disappears, joint mobility improves, but the conservative treatment may not always stop the development of the disease. Of particular importance are hygienic measures aimed at fully unloading the hip joint and avoiding any strain. Working conditions should change, sport activities that involve stress on the hip joint should be stopped and, just in case, a walking cane should be used (13). A walking cane carried in the hand opposite the affected hip and on which the patient rests associated with the arthritic hip support release approximately two-thirds of the pressure exerted on the articular surface. Fighting obesity and overweight is also important in order to avoid hip joint overload. This hygienic treatment should be associated with anti-inflammatory and analgesic medication.

Kinesitherapy aims at maintaining a good joint and general mobility and tonic muscles, prerequisites for a successful rehabilitation. Kinesitherapy is associated with periodical balneophysical therapy (14).

Modern surgery offers multiple ways to stop the development of osteoarthritis. Conservative and functional surgical procedures (osteotomies and changing relationships between the articular surfaces)

give the possibility of changing the way the mechanical factors act upon the hip (15). They manage to increase the contact area between the two joint ends and thereby to lessen to a large extent the pressure exerted on this surface. As a result of the biological effect of improving local circulation, osteotomies relieve pain.

Conservative surgery (osteotomy, arthroscopic debridement, arthrodesis, partial arthroplasty) or total hip replacement surgery must be associated with a prolonged conservative and rehabilitative treatment.

MATERIAL AND METHODS

The study was conducted between January 2012 and December 2012, on a series of 27 coxarthrosis patients diagnosed at the Rheumatology Clinic of the Iasi Rehabilitation Hospital. The patients were admitted for 10-15 days and were recruited based on the type of joint damage, age, degree of patient compliance, and other factors observed at individual assessments.

RESULTS AND DISCUSSION

Of the 27 patients, 11 (40.74%) had primary bilateral coxarthrosis with pain and functional decompensation. Muscle testing, the testing of the muscles that stabilize the coxofemoral joint, showed a value of 4. In these patients, pain diminished or alleviated at rest and they were walking with a limp. The degrees of coxofemoral joint mobility were affected by the arthritic process, especially in internal and external rotation movements, and they were associated with contracture of adductor and pelvitrochanteric muscles (Fig. 3).

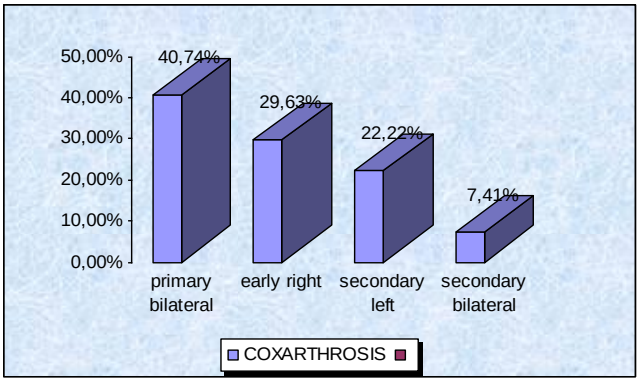

Fig.3. Types of coxarthrosis in the study group

Kinesitherapy and massage were effective in relaxing the coxofemoral joint and correcting or preventing the incorrect body position. Medical gymnastics resulted in restored mobility of the lower limb and the progressive increase in muscle strength was due to practicing passive mobilization, self-mobilization, active mobilization and movements for toning the lower limb muscles. A cane was used when walking, the cane being held in the hand corresponding to the healthy hip.

Analgesics and anti-inflammatory drugs, vasodilator agents and anti-contraction medication were used in fighting pain, controlling muscle contracture, and preventing vascular disorders.

Of the 27 coxarthrosis patients, 8

(29.63%) had early coxarthrosis, right hip, presenting mild or moderate pain and instability in motion. Testing of the muscles that stabilize the coxofemoral joint showed a value of 5, with a mild contracture of adductor and pelvi-trochanteric muscles that limits the mobility of the hip. Without cane, they were walking with a limp when tired or on longer distances. The treatment methods used were kinesitherapy, passive mobilization, self-mobilization and active mobilization by progressive resistance exercises, toning the lower limb muscles if hypotonic, toning the hamstring and gluteal muscles through isometric or isotonic exercises. The stage objectives were to adapt to effort and to resume walking. Physiotherapy, thermotherapy, hydrotherapy and, if possible, hydro-kinesitherapy have also been recommended.

Six (22.22%) of the 27 patients had coxarthrosis, left, secondary to aseptic femoral head osteonecrosis with incorrect position of the lower limb and sometimes with pain in the lumbosacral area. Often the patients were forced to use walking cane. Muscle testing showed lower values in extensor abductor and internal rotator muscles. This accounted for the altered stance in flexion and adduction.

Of the 27 coxarthrosis patients, 2 (7.41%) presented bilateral coxarthrosis secondary to acetabular insufficiency. Patients reported mixed arthralgia in the coxofemoral joints, often associated with back pain or knee pain. Isometric contractions for the quadriceps muscle, correcting the trunk and pelvis position by means of exercises for paravertebral and abdominal muscles, hydro-kinesitherapy, active and passive mobilization, massage, toning muscles aimed to control pain, maintain mobility and muscle strength. Patients had a good outcome and regained stability, mobility and muscle strength in both lower limbs.

The kinesitherapy program conducted during our study was individualized and aimed to relieve pain (through hydrotherapy, electrotherapy and thermo-therapy) by achieving a good stability of the hip joint, providing functional mobility angles, and avoiding incorrect body position.

The analysis of the data on the achieved joint and muscle balance showed an improvement in joint mobility, normal muscle strength values, and a good social and professional integration of the patients.

CONCLUSIONS

Researchers have shown that early use of kinesitherapy had good results in coxarthrosis patients for the functional recovery of the affected area due to the individualization of the kinesitherapy procedures according to patient's response to treatment.

The proper assessment of joint function impairment, pain, radiological injury quantification, patient compliance has allowed an accurate decision making on therapy and long-term rehabilitation methods.

The complex therapeutic, educational, and physical kinetic and drug regimen associated with close doctor-patient cooperation has been shown to manage this disease from its onset.

NEWS

A CLINICAL AND HISTOLOGICAL REPORT OF A TOOTH WITH AN OPEN APEX TREATED WITH REGENERATIVE ENDODONTICS USING PLATELET-RICH PLASMA

Regenerative endodontic procedures are biologically procedures which aim to regenerate the damaged pulp-dentin complex, resorbed root, cervical or apical dentin by stimulating of the proliferation of remaining vital tissues under favorable conditions. The conventional method consisted of inducing bleeding into the pulp canal by mechanically irritating the periapical tissues. The created blood clot operated as a matrix for the growth of new tissues into the pulp canal. However, this procedure implied discomfort for the patient because of the irritation of the periapical tissues. Understanding of the physiological roles of platelets in wound healing has led to the idea of using platelets as a scaffold for regenerative endodontic therapy. Platelet-Rich Plasma (PRP) consists of a limited volume of plasma enriched with platelets, obtained from the patient. The purpose of this case report was to present the clinical, radiographic, and histological findings of a regenerative procedure using platelet-rich plasma (PRP) 14 months after the procedure. A 12-year-old boy whose maxillary second premolar tooth had been treated with regenerative endodontics was seen with a chief complaint of pain and sensitivity to cold. After clinical and radiographic examinations, a pulpal diagnosis of reversible pulpitis and normal periapical tissues was made for this tooth. Because of the patient's complaint and his guardian's insistence on either a root canal treatment or an extraction, a root canal treatment was performed in this tooth. After entry into the root canal, the soft tissue present in the canal was removed with the aid of a large barbed broach and examined histologically. Examination of the tissue removed from the root canal of this tooth revealed the presence of a vital pulp-like vital connective tissue. There was no evidence of bone in the specimen. Very few inflammatory cells were noted in the periphery of the specimen. Based on these findings, the authors concluded that pulp-like tissue could be generated in human teeth with the use of PRP as a scaffold in regenerative endodontic procedures **(**Torabinejad M, Faras H. A clinical and histological report of a tooth with an open apex treated with regenerative endodontics using platelet-rich plasma *J Endod* 2012; 38(6); 864-8).

STRESS: FROM SYMPTOM TO DISEASE (Abstract). **Aim:** To evaluate the presence and role of stress in causing diseases. **Materials and methods**: We conducted a 6-month study in patients who presented for the first time with a series of symptom and tried to look for an organic cause of those symptoms. We wanted to see the impact of stress in everyday life and its role in causing various diseases. **Results:** The obtained results showed a female predominance in terms of seeking medical advice and that the most affected age group was 20-30 years, accounted for by the start of socio-professional issues. The psycho-behavioural symptoms were the most prevalent, followed by the gastro-intestinal ones. The presence of stress had left its mark on these events, fact proven by the lower rate of organic pathology. **Conclusions:** Stress awareness must guide us in medical practice as to avoid under- or over-diagnosis. **Keywords:** STRESS, HYPERTENSION, METABOLIC DISORDERS.

Hans Selye (1) used the term „stress" in 1950 to designate a set of body reactions to an external action exerted by a wide range of causative agents: physical agents (trauma, burns), chemical agents (chemical substances from food, air, water, work environment, drugs), and biological agents (external - viruses, bacteria, parasites etc. - or internal - endocrine, immune and mental factors, personality traits etc.) resulting in various morphofunctional changes.

Depending on its action upon the body, stress is classified into two categories: eustress and distress. Eustress is produced by stress factors that have beneficial action on the body and does not generate harmful reactions (2). This stress is positive and moderate, and helps a person perform at a higher level and achieve his goals. Distress is caused by stress factors that cause overexertion and generate negative effects. This is the intense and prolonged stress which exceeds the adaptation level, leading to poor performance. It may result in diminished normal functions or even diseases (3).

Stages of stress are: alarm, resistance, and exhaustion (4).

Potential effects of stress can be grouped into five broad categories, namely (5):

• *Subjective effects*: anxiety, aggression, apathy, boredom, fatigue, malaise, low self-esteem, anxiety, loneliness;

• *behavioural effects*: predisposition to accidents, alcoholism, abuse of coffee, tendency to eat and/ or to smoke excessively, impulsive behaviour;

• *cognitive effects*: decrease in the ability to take rational decisions, poor concen-

tration, decreased attention, hypersensitivity to criticism, mental blocks;

• *physiological effects*: increased blood sugar, pulse, blood pressure, dry mouth, cold sweat, dilated pupils;

• *organizational effects*: absenteeism, low productivity, isolation, job dissatisfaction, reduced responsibilities, reduced loyalty to the organization, resignations.

If a person already has a disease such as cardiovascular disease or a form of diabetes, the increased muscle tension and increase blood sugar, caused by stress, can aggravate the suffering. Studies have shown that prolonged stress is correlated with the onset of illness or disease. The degree to which stress contributes to disease development is still unclear (6).

I. CORRELATIONS OF STRESS WITH SOME DISEASES

1. Hypertension (6, 7). Because blood pressure sometimes increases in response to a stressor, researchers have suspected a possible link between stress and hypertension. Chronically elevated blood pressure levels - which can lead to cardiovascular disease - are thought to be stress-related. Studies showed that individuals who work under great psychological pressure (e.g. airline pilots) or in a high-stress environment (high workplace noise levels) tend to develop higher blood pressure than those who live and work in an atmosphere less fraught with tension.

2. Forms of diabetes and (digestive) ulcer (6, 7). Both diabetes and ulcer are directly linked to stress. In diabetes, when stress raises blood glucose level, pancreatic cells react by producing insulin. Chronic stress can damage these cells, which cannot be replaced, severely affecting the ability of the pancreas to produce the insulin needed to control blood glucose. This results in an increased risk for the onset of diabetes especially in those individuals who are genetically predisposed to this disease (9). Digestive ulcer is caused by excessive secretion of gastric acid, producing severe pain and often leading to gastrointestinal bleeding or perforation. Nonetheless, we do not know the real cause of digestive ulcer, but we are sure that stress can aggravate this condition.

3. Mental disorders (9, 10, 11). Stress generates emotional struggles, which may aggravate existing emotional disorders.

4. Bulimia nervosa and anorexia nervosa (12). Ten-times times more common in women and with a prevalence of 1-3% (bulimia) and 0.5% (anorexia), these two represent extreme forms of eating behavior disorders, the causes of which are not known precisely; beside heredity, stress and emotional disturbances play an important role in developing bulimia and anorexia. Many times, stress can lead to depression which is frequently characterized by reduced appetite and weight loss.

II. ROLE OF INFORMATION IN STRESS

Anything that overwhelms the adaptation mechanisms can cause a stress reaction. But this always happens through information. Whether physical, chemical or psychological factors are involved, the information generated by these must reach the reticular substance, the cortex, the limbic system and the hypothalamus, in order to trigger stress reaction (5).

Information is the one that influences the synthesis of neuro-pituitary hormones, which will influence, in their turn, the secretion of peripheral hormones, which will then act on different tissues. This applies

both to psychological stress and physical stress when the information is triggering, ultimately, the neuro-endocrine stress response. The only difference is the fact that in psychological stress the information is coming from outside, and in physical stress, the information is coming from inside the body, due to damage caused by stress factors. Therefore, the information itself can be a stressful factor. Mental stress is actually a stress information because it is made of the information provided by stress factors. After being evaluated as a harmful or potentially harmful factors, stress causes adrenal activation through cognitive and affective processes (13). R.S. Lazarus emphasizes the fundamental role of cognitive state in the stress process, which is evaluated as a harm/loss, a threat, or a challenge. The anticipatory nature of psychological stress links it more to the feedbefore mechanism, unlike physical stress which involves more feedback mechanisms. Psychological stress occurs when feedbefore mechanism is outdated and cannot find in its repertoire an appropriate strategy to preserve stability in the conditions that generated the information (14).

MATERIAL AND METHODS

Attached to the theoretical data, we conducted a 6-month prospective study to determine the impact of stress in everyday life and its role in causing various diseases. The study included patients presenting a series of symptoms and we tried to find the organic cause of these symptoms.

Inclusion criteria: $\geq$ 18 years; consent to participate in the study; onset symptoms; absence of previously diagnosed organic condition; presence of stress.

Patients underwent a thorough medical history, during which no attempt at inducing stress was made but was carefully looked for it in their medical records. Then patients were asked to fill out a questionnaire specifically developed into a language that respondents understand, as a way to find out whether they experienced any kind of stress.

The questionnaire was based on Holmes and Rahe stress scale. A score of 0-150 was interpreted as no significant problems; 151-200 – mild damage; 201-300 – moderate damage; over 301 sever damage.

After filling out the questionnaire, depending on the findings, patients were referred to a laboratory for full investigations aimed at determining the organic cause responsible for their complaints.

The series included 246 patients presented with the following symptoms: digestive symptoms (epigastric pain, heartburn, loss of appetite, abnormal transit); cardiovascular symptoms (palpitations, high blood pressure, and headache); psychiatric symptoms (disturbances of attention and concentration, nervousness, emotional labiality, depressive state, agitation, restlessness); weight gain.

In patients presenting digestive symptoms, biochemical and hematological tests, including Helicobacter Pylori testing, were performed. If the results were inconclusive, a contrast barium enema in Trendelenburg position and upper endoscopy were also performed.

For those with cardiovascular symptoms blood pressure and heart rate were repeatedly measured, and an electrocardiogram and echocardiography were performed to identify a possible cardiovascular abnormality. The patients with psychiatric symptoms were referred to a psychiatrist and psychologist for assessment.

RESULTS AND DISCUSSION

The study series included 182 women

(73.98%) and 64 men (26.01%) and age distribution can be seen in table I. The distribution of patients according to symptoms is presented in table II.

The results of the stress questionnaire are presented in table III.

TABLE I

Age-group distribution

Age groups	Years					
	21-30	**31-40**	**41-50**	**51-60**	**≥ 61**	**Total**
Number	163	61	19	2	1	246
Percent	66.26	24.79	7.72	0.8	0.4	100

TABLE II

Distribution of patients according to symptoms

Area	Subjective (No)	Objective (No)	Diagnosis
Digestive	66	13	Gastroduodenal ulcer
Psychiatric	129	0	-
Cardiovascular	51	9	Hypertension

TABLE III

Results of stress questionnaire

Results	Patients	
	Number	**Percent**
Without significant problems	83	33.73
Mild damage	86	34.95
Moderate damage	54	21.95
Severe damage	23	9.34

Of the 246 patients who presented various complaints, in only 22, less than 10%, an organic cause was found.

From the obtained results, it can be seen that there is a female predominance in terms of seeking medical advice and that the most affected age-group is 20-30 years, explained by the start of socio-professional problems. It can be clearly noticed the prevalence of the psycho-behavioural symptoms followed by the gastro-intestinal ones, and that the presence of stress has left its mark on these events, fact proven by the low rate of organic pathology.

The relationship between different diseases and stress is known and proven for many diseases. Clinicians and scientists have studied and debated the contribution of stress to the inflammatory process in bowel disease (IBD) since 1930 but no definitive conclusion has been reached. Patients with inflammatory bowel disease are near reaching a consensus, with 74% believing that psychological factors have played a role in triggering the onset of disease or relapse of their illness (15).

Stressful life influences the cardiovascular system and the atherosclerosis process. As part of the reaction to stressful life situations, notably those associated with tension, frustration, conflict, anxiety and depression the cardiovascular apparatus exhibits both hyper and hypo dynamic responses. These include alterations in the rate, rhythm, force and magnitude of cardiac contraction, change in the configuration of heart action potential, and modification in the peripheral circulatory resistance (16). Carissa A.L. et al (17) showed in their study that the adolescents exposed to chronic, negative stressors that worsen over time may show heightened cardiovascular reactivity that puts them at risk for subclinical atherosclerosis.

Reviews of research on life stress and depression unanimously conclude major life events precede the onset of many, if not the majority of depressive episodes (Kessler, 1997; Mazure, 1998; Tennant, 2002 ; Paykel, 2003; Hammen, 2005) (18).

CONCLUSIONS

This study proves that about 10% of the patients presenting to an ambulatory unit and which have suffered a stress whatever its nature have an organic cause of symptoms. We do not want to underestimate the presence of diseases among the population, but over-diagnosis is a problem of attitude. An additional laboratory investigation does nothing else but to confirm or infirm a diagnosis. The presence of a disease is an additional stress for anyone, as is uncertainty. Stress factors are everywhere and stress is not sparing anyone. We must be aware of its existence and act accordingly.

DERIVATIVES OF IBUPROFEN IN PREVENTING COLON CANCER

The cancer chemopreventive properties and gastrointestinal toxicity of ibuprofen are well documented. Ibuprofen and a modified derivative (phosphor-modified ibuprofen or p-ibuprofen) were used in a chemically induced model of colon cancer by Ouyang et al. Fisher 344 rats were injected with azoxymethane and treated with either ibuprofen (500 ppm) or p-ibuprofen (900 ppm) for 20 weeks to observe aberrant crypt foci (ACF) or 40 weeks to evaluate tumor incident and multiplicity. β-catenin and p65 were measured in colonic tissues by immunofluorescence staining. Equal molar doses of ibuprofen (75 and 670 mg/kg) and p-ibuprofen (135 and 1215 mg/kg) were administered to rats for 7 days to assess acute toxicity. At week 20, p-ibuprofen and ibuprofen significantly reduced the multiplicity of ACF compared with the control ($p < 0.05$) by 31.2 and 37.9%, respectively. At week 40, p-ibuprofen and ibuprofen reduced the multiplicity of colon tumors compared with control ($p < 0.05$) by 47.2 and 56.6% respectively. Equal molar concentrations of ibuprofen (670 mg/kg) and p-ibuprofen (1215 mg/kg) resulted in stomach ulceration in 85.7% and 14.3% of rats, respectively ($p < 0.05$). Immunofluorescence staining and western blot analysis demonstrated that both ibuprofen and p-ibuprofen suppressed β-catenin nuclear translocation in colon cancer cells. In addition, p-ibuprofen, but not ibuprofen inhibited NF-kB activation in colon cancer cells. Collectively, these results suggest that p-ibuprofen is a potential effective novel drug for long-term use in colon cancer prevention (Ouyang N, Ji P, Williams JL. A novel NSAID derivative, phospho-ibuprofen, prevents AOM-induced colon cancer in rats. *Int J Oncol* 2013; 42(2): 643-650).

EVALUATION OF TUMOR RESPONSE TO SYSTEMIC THERAPY IN HEPATOCELLULAR CARCINOMA

EVALUATION OF TUMOR RESPONSE TO SYSTEMIC THERAPY IN HEPATOCELLULAR CARCINOMA (Abstract): Evaluation of tumor response (the change in tumor volume) represents the basis for assessing therapeutic efficacy. Furthermore, objective response and progression are endpoints in clinical trials. *Response Evaluation Criteria in Solid Tumors* (RECIST) is an assessment tool derived from the conversion of quantitative imaging observations. Version 1.1 has been validated and its criteria are useful in all studies intended to assess objective response, disease stabilization and tumor progression, or time to progression analysis. In addition to changes regarding the disease assessment criteria of measurable and non-measurable lesions, the new system integrates volumetric assessment and functional imaging. The RECIST's utility system follows from the applicability in clinical trials and the possible use in clinical practice. However, adapting it to assess liver tumors requires evaluation in prospective trials. **Keywords**: HEPATOCELLULAR CARCINOMA, IMAGING, TUMOR RESPONSE

Primary liver tumors are the 5th most common human cancer and the third cause of cancer mortality worldwide. These data do not only indicate a high frequency, but also emphasize their extreme lethality. Of the primary liver tumors, *hepatocellular carcinoma* (HCC) is the most common, accounting for 80-90% of the total (1).

The highest incidence is observed in East Asia, followed by Central Africa, Southeast Asia, Pacific Islands, East Africa, West Africa, Southern Europe, South Africa, Eastern and Western Europe, North America and South Australia, Northern Europe and Central America. The incidence in Europe is below 10 per 100,000 populations (2). In Romania, HCC is the 10th most common cancer and the 7th in terms of mortality (3).

About 80% to 90% of cases develop from underlying chronic liver disease. Cirrhosis is a late stage of many liver diseases, including viral hepatitis, alcoholic liver disease, nonalcoholic steatohepatitis, hemochromatosis, primary biliary cirrhosis, autoimmune liver diseases, and metabolic

disorders. However, primary biliary cirrhosis and autoimmune liver diseases rarely lead to HCC (2).

Regarding the biology of HCC, currently three main altered signaling pathways responsible for the appearance and progression of this cancer are known. Data provided by Spangenberg and Liu (4, 5) show that the main pathways are mediated by TGF-β (transforming growth factor-β) and Wnt, centered on Akt signaling cascades and pathways, expressed in indolent cancers initiated by β-catenin gene mutations. Unfortunately, blocking Wnt-β-catenin pathways is not possible at present. However, the Ras-Raf-MAPK and Akt pathways can be targeted with such pharmacological agents as mTOR (mammalian target of rapamycin) inhibitors.

Clinical studies have evaluated the cytotoxic chemotherapy alone or in combinations and have not demonstrated significant improvements in overall survival and time to progression. The research in the molecular pathogenesis of HCC was directed to identify intercellular signaling pathways, because the neoplastic disease arises from aberrant mechanisms of gene control and abnormal protein expression. New techniques for assessing the tumor phenotype may be used for tailoring new therapeutic approaches. HCC is a highly vascularized tumor, with an increase in microvascular density and increased levels of VEGF. As a consequence, various trials have used sorafenib (antiangiogenetic predominant mechanism) or bevacizumab alone or in combination with other drugs (6, 7, 8, 9, 10, 11, 12, 13, 14).

Evaluation of tumor response following the use of such antiangiogenetic therapies became a major issue. Unlike cytotoxic chemotherapy, whose effectiveness can be assessed by reduction (one or two-dimensional) in tumor size, the tumor response to antiangiogenetic therapies is usually expressed by extending tumor necrosis without a significant impact on tumor size. Moreover, the combination of the two above mentioned types of medication makes the evaluation of therapeutic efficacy difficult (15, 16).

To standardize tumor response to molecular therapies and to simplify the evaluation methods, Eisenhauer et al. (17) proposed changes in RECIST criteria (Response Evaluation Criteria in Solid tumors). RECIST 1.1 criteria aimed at assessing primary tumor response in clinical trials (less useful in practice) where the primary endpoint is the objective response. It defines four main categories of response for measurable lesions: complete response - CR (disappearance of all tumor lesions), partial response - PR (30% reduction of the measured maximum diameter), progressive disease - PD (20% increase in the maximum diameters but not less than 5 mm – fig. 2), and stable disease - SD (criteria for partial response or progressive disease are not met).

Major changes included in version 1.1 were:

- the number of lesions required to define tumor response was reduced from 10 to 5 (total) and from 5 to 2 (per organ);

- to define complete response in lymph nodes, it is possible to evaluate them by pathological exam;

- progression of disease requires an increase of target lesion of at least 5 mm;

- the lymph nodes are to be measured in the short axis and if the size is greater than 15 mm it may be considered a target lesion;

- the nodes with short axis decreased under 10 mm after treatment are to be con-

sidered as normal lymph nodes .

Also, the new guide has introduced information on the evaluation by functional imaging. These criteria, although universal, can be modified and adapted to each trial individually (17).

Initial assessment (baseline) aims to establish tumor or lymph node lesions and to fit them into measurable lesions (target) or non-measurable (non-target). The criteria necessary to define target lesions are: minimum size of 10 mm assessed on a CT scan (fig. 1) with sections of 5 mm or less, 10 mm for clinically measurable lesions, 20 mm if the assessment is done by chest radiograph, and 15 mm in short axis for nodes (measured by CT). Non-measurable lesions consist of all the tumors that do not meet the above criteria and truly non-measurable lesions like ascites, pleural or pericardial effusion, leptomeningeal metastases, inflammatory breast cancer, carcinomatous lymphangitis, and purely blastic bone metastases. Cystic lesions or previously treated lesions by local procedures should be avoided. For a correct assessment, the same imaging method should be used from baseline throughout the study (17).

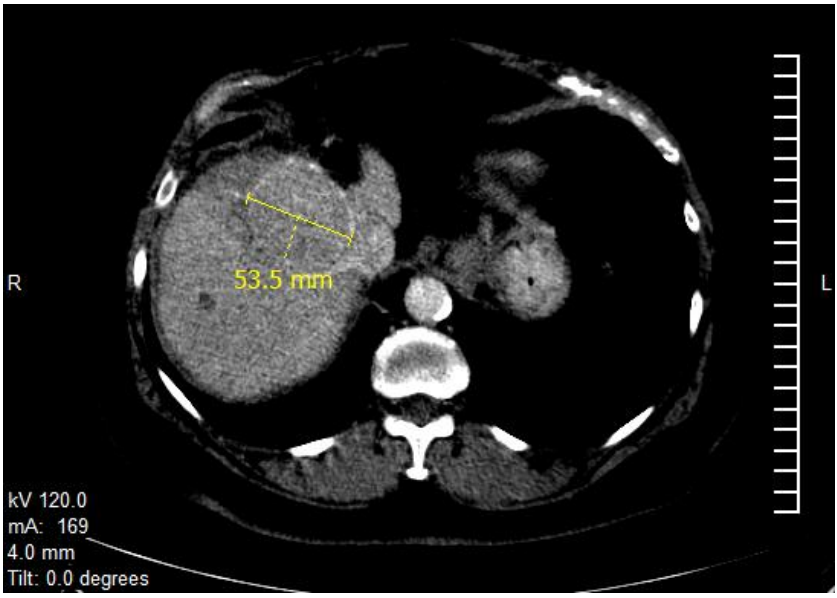

Fig. 1. Initial assessment of a patient with liver cancer (T1=53. 5 mm)

The course of non-measurable lesions can be classified into 3 categories:

- complete response - CR - defined as disappearance of all lesions and reduction in axis diameter of lymph node below 10 mm;

- incomplete response / stable disease - IR/SD - defined as the persistence of non-target lesions or high levels of tumor markers;

- progressive disease - PD - defined as unequivocal progression (17).

The time interval between assessments should be about 6-8 weeks and coincide with the completion of a treatment cycle. To define the clinical benefit, the response should be maintained over a period of time of at least 16 weeks (progression free survival PFS16). To evaluate the effectiveness

of therapies in terms of PFS, all patients in the study must have measurable disease. In particular situations, assessing the response may be impossible: premature discontinuation of treatment due to toxicity, death, patient refusal. The study results should be based on reporting the results for all eligible patients and not only based on the selective processing of the "evaluable" patients (17).

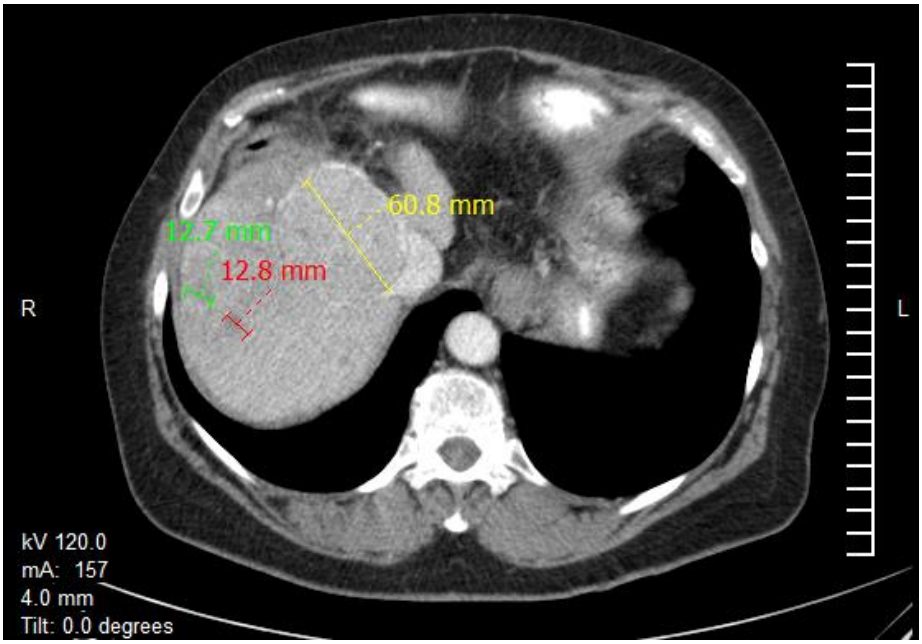

Fig. 2. Progression of disease – new lesions

Since RECIST criteria were originally designed to evaluate tumor response in cytotoxic treatments, *European Association for the Study of Liver* (EASL) recommended the use of mRECIST (modified RECIST) criteria in clinical trials (18, 19). Thus, the measurement of lesions is done only to viable tumor tissue, which captures the contrast substance in the arterial phase, and pleural effusions and peritoneal cytology require confirmation for progression of disease to be declared, portal lymph nodes are considered involved if the short axis is greater than 2 cm, portal vein thrombosis is considered non-target lesion, and a new lesion defines progression of disease if the maximum diameter is at least 1 cm and captures the contrast agent. The study by Ahsun Riaz et al. proved a better match between mRECIST and pathologic response than RECIST and WHO systems. If WHO and mRECIST are combined, the results have better value than any method individually. Patients previously treated by local methods should be evaluated carefully, taking into account the possibility of artifacts induced by lipiodol, clips (18, 19).

Ultrasonography (US) is the initial examination performed in most patients with suspected liver masses because it is faster, has satisfactory accuracy, and is a noninvasive method. Moreover, US provide real-

time imaging and can be used for guided biopsies. By contrast enhanced US (CEUS), focal liver lesions can be diagnosed based on their specific vascular characteristics. CEUS has a sensitivity of 94% and a specificity of 93% for the diagnosis of HCC. The main disadvantage is the dependence on operator and patient, because obese patients can be difficult to scan and the reproducibility is limited. Based on these drawbacks of US, EASL guidelines recommended the use of CT or MRI in clinical trials. However, during the follow-up period, after local treatment with curative potential, the US can be used after the first year without evidence of recurrence. Still, during the first year after treatment, CT or MRI needs to be performed every 3 months and if no relapse is observed, US may be used (2, 18, 19).

Currently, CT is still the gold standard for liver imaging. Therefore, in clinical trials, as well as in daily practice, the major goals of liver imaging remain:

- to assess the number and size of lesions;
- to locate the lesions;
- to suggest the nature of lesions (malignant vs. benign);
- to identify the origin of lesions (primary vs. secondary);
- to evaluate the damage to liver parenchyma;
- to assess the extrahepatic disease;
- to evaluate the response to treatment (2).

Moreover, with the new techniques of liver resection and partial transplant, there is a need for an accurate assessment of the liver graft.

In conclusion, there is no absolute consensus regarding the optimal strategy for the evaluation of liver tumors in clinical trials. The way we choose to evaluate the response is based on clinician's requirements, the availability of equipment, patient's status, and the experience of the staff.

NEWS

PYRIDOMYCIN A NEW DRUG FOR TUBERCULOSIS

Tuberculosis is a serious public health issue. Increased frequency of cases caused by first-line antituberculosis drugs resistant strains requires identification of new therapeutic alternatives. First described in 1953, pyridomycin is a bactericidal agent against mycobacteria without action on other bacteria. It is a "natural isoniazid" produced by *Streptomyces pyridomyceticus* or *Dactylosporangium fulvum*. A recent study by Ruben et all. revealed the mechanism by which this antibiotic kills *Mycobacterium tuberculosis*. Like isoniazid, pyridomycin binds NADH dependent enoyl (ACP)-reductase InhA and inhibits InhA which results in the inhibition of mycolic acid synthesis in *M. tuberculosis*. Unlike isoniazid, pyridomycin action does not depend on KatG catalase-peroxidase. Thus isoniazid-resistant strains (due to alteration of KatG activity) retains sensitivity to pyridomycin, thus opening new avenues for drug development. (Ruben C. Hartkoorn, Claudia Sala, João Neres et al. Towards a new tuberculosis drug: pyridomycin - nature's isoniazid. *EMBO Molecular Medicine*, 2012, 4(10):1032–1042).

CLINICAL FEATURES AND COURSE OF BACTERIAL MENINGITIS IN CHILDREN (Abstract): **Aim**: To analyze the clinical features and course of and to define the risk factors for bacterial meningitis in children. **Material and Methods**: Retrospective study of 100 cases of bacterial meningitis in patients aged 0-18 years admitted to the Iasi Infectious Diseases Hospital between 2005 and 2010. **Results**: We found a clear prevalence in male children (58%) from rural area (67%), with the highest incidence in the age group 2-5 years. A significant percentage of patients (43%) had previous hospitalization, condition which is known as predisposing factor for bacterial meningitis, the most common being ear infections (20%) and height and weight deficit (9%). 71% of patients were admitted within the first 48 h. The most common onset clinical manifestations were fever (84%), vomiting (70%), signs of meningeal irritation (59%), somnolence (23%), loss of appetite (19%), and coma in 5% of patients. In 36% of cases CSF was opalescent with moderate pleocytosis (35%); in 29% of patients CSF albumin level ranged between 0.7-1.0 g, the majority presenting normal glycorahia (71%). In only 21% of cases the microbial agent was identified (pneumococcal and meningococcal etiology, 8% and 6%, respectively). The course was generally favorable, and mortality rate was low (5%). Complications occurred in 3% of patients consisting in hydrocephalus and brain abscess. **Conclusions**: Bacterial meningitis remains a disease with potentially severe course. Clinical onset, most commonly atypical in children, requires differential diagnosis at the time of admission in order to initiate the most appropriate antibiotic therapy.
Key words: CHILDREN, BACTERIAL MENINGITIS, PARTICULARITIES.

The number of bacterial meningitis cases is estimated at over one million per year worldwide, with more than two thirds of these occurring before 5 years of age. Acute bacterial meningitis (ABM) in children continues to be associated with high morbidity and mortality, despite progress in terms of etiological therapy. In all countries, whether industrialized or developing, the risk of epidemics remains a topical issue. Bacterial meningitis in children is, in all cases, a therapeutic emergency, involving allegations of early clinical diagnosis to be confirmed by CSF examination.

The etiologic agent varies with age, immune system, immunization status and the geographical region. *Haemophilus influenzae* type b (Hib), *Streptococcus pneu-*

moniae, and *Neisseria meningitidis* cause most cases of acute bacterial meningitis (ABM) in children, but epidemiological data are changing rapidly because of immunization practices and changing patterns of bacterial resistance.

Before the introduction of an effective vaccine, *Haemophilus influenzae* (Hi) was the most common etiologic agent before 5 years of age (about 45% of cases). In those countries where Hib vaccine is part of the routine infant immunization, Hib was almost eradicated (1, 2).

Vaccines against pneumococcal and meningococcal diseases have changed significantly the disease profile (3).

Streptococcus pneumoniae (Sp) is involved in about 20% of child MB (about 30% before one year of age, and 40% before 6 months in developed countries). Two features are important to be remembered: a) Sp is common in patients with hemoglobinpathies and splenectomy; b) the increasing rate of penicillin resistance requires rigorous epidemiological surveillance of Sp susceptibility profile. Vaccination at 2 months aims at preventing early infections. In countries where routine pneumococcal immunization was introduced, an increase in invasive pneumococcal disease due to non-vaccine serotypes was not reported (4, 5).

Neisseria meningitidis (Nm) is responsible for severe MB: fulminant meningococcemia and meningitis. The overall incidence of Nm meningitis is approximately 30% of cases (60% over 5 years, 25% before this age) with deadly epidemics reported especially in the "meningitis belt" of sub-Saharan Africa, where Nm serogroup A affects up to 1% of the population. Nm serogroup B predominates in Europe and Nm serogroup C has an increased frequency in France. Effective vaccination against serotypes A and C has reduced the number of secondary cases and epidemics (6).

MATERIAL AND METHODS

The present study aims at evaluating the clinical and biological features and the trends in the course of bacterial meningitis in children in order to optimize the first-line antibiotic therapy for this category of patients. Our study is a retrospective analysis which included 100 patients aged 0-18 years diagnosed with bacterial meningitis at the Iasi Infectious Diseases Hospital Iasi between 2005 and 2010.

The diagnosis of bacterial meningitis was based on clinical and laboratory criteria.

A t-test, Fisher's exact test, or Pearson chi-square test were used where appropriate, and a p-value of < 0.05 was considered significant.

RESULTS

During the 6-year study period, 354 patients with bacterial meningitis, of which 28.24% were children, were admitted to the Iasi Infectious Diseases Hospital. In the interval 2005-2010 the number of pediatric bacterial meningitis cases was relatively constant, peaking in 2008 (24%).

Comparing the incidence of bacterial meningitis in the two genders, a slightly higher value was observed in males (58% vs. 42% in women). Age of patients ranged between 0 and 18 years, with a mean age of 8 years. Bacterial meningitis was more common in the age group 1-5 years (28%), with lower but comparable rates in the age group 6-11 years (27%) and 0-12 months (25%).

Upon admission we noticed that the predisposing factors for bacterial meningitis were ENT infections (20%), height and weight deficit (9%), digestive system infections (5%), trauma (4%), protein-caloric

malnutrition (4%), and ventriculoperitoneal shunt (1%). 71% of patients were admitted within 48 hours after the onset. The most common onset clinical manifestations were fever (84%), vomiting (70%), signs of meningeal irritation (59%), somnolence (23%), loss of appetite (19%), and coma in 5% of patients. CSF examination revealed a turbid macroscopic appearance in 36% of cases, clear CFS in 33%, and in only 13% of cases a typical purulent appearance. 35% of cases had a moderate pleocytosis in CSF, and increased cellularity > 1000/mm³. Glycorahia was found low (0.2 to 0.3 g / l) in almost a half of patients (47%).

Of the 100 children diagnosed with bacterial meningitis, in only 21% the infection was microbiologically documented: in 8% of patients the causative agent was pneumococcus, meningococcus was isolated in 6% of patients, and *Haemophilus influenzae* in 4% of cases. Two (2%) cases of bacterial meningitis with Gram-negative and 1 case (1%) of staphylococcus meningitis were reported. These small positivity rates are most likely due to the fact that more than half of patients received antibiotics prior to admission.

In this study we analyzed the age-related clinical and laboratory features of bacterial meningitis and found significant statistical differences with regard to meningeal irritation syndrome and vomiting at the onset (tab. I, II).

TABLE I

Age-group distribution of onset symptoms

Clinical manifestation	Age group 1-5 Years (n=28)	Age group 6-11 years (n=27)	p
Fever	27 (96.42%)	25 (92.5%)	0.51
Meningeal irritation syndrome	11 (39.2%)	22 (81.48%)	0.001
Vomiting	4 (14.48%)	19 (73.37%)	0.00002
Anorexia	21 (75%)	16 (59.29%)	0.213
Somnolence	20 (71.42%)	19 (73.37%)	0.931
Seizures	14 (50%)	9 (33.33%)	0.210
Coma	2 (7.14%)	3 (11.11%)	0.608

TABLE II

Age group distribution of CSF characteristics

CSF parameters	Age group 1-5 years	Age group 6-11 years	p
Purulent	8 (28.57%)	5 (18.51%)	0.380
Opalescent	11 (39.28%)	12 (44.4%)	0.698
clear	9 (32.14%)	10 (30.07%)	0.702,
100- 500 cel/mm	7 (25%)	8 (29.6%)	0.699
500-1000 cel/mm3	6 (21.4%)	4 (14.81%)	0.524
1000-2000 cel/mm3	10 (35.71%)	8 (29.6%)	0.630
>2000 cel/mm3	5 (17.85%)	7 (25.92%)	0.468
Protein 0,7-1g/l	4 (14.28%)	7 (25.92%)	0.28
1-3 g/l	11 (39.28%)	12 (44.4%)	0.698
3-5 g/l	13 (46.42%)	8 (29.6%)	0.199
Normal CSF glucose	10 (35.71%)	12 (44.44%)	0.508
Low CSG glucose	18 (64.28%)	15 (55.5%)	0.508

To be effective, the etiological treatment must have a rapid microbicidal effect. The majority of patients (60%) received a single beta-lactam antibiotic (ampicillin, ceftriaxone or meronem). 26% of cases were treated with an association of two antibiotics, the most commonly used as first-line being ampicillin + ciprofloxacin, ceftriaxone + ciprofloxacin, or vancomycin + ciprofloxacin (fig. 1). A small number of patients (14%) required a combination of more than two antibiotics, based on CSF culture results, sensitivity testing, and subsequent clinical course.

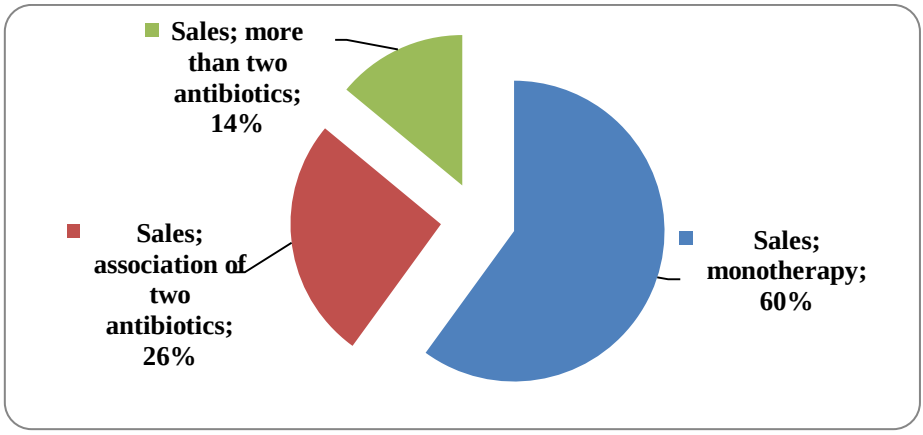

Fig.1. Etiological treatment of bacterial meningitis in children

The course of bacterial meningitis in the studied group was generally favorable; only few cases developed neurological complications (3%) consisting of hydrocephalus and brain abscess. Mortality rate was low - 5%. Unfavorable course was associated with severe general status and age at onset (all children in coma upon admission and those belonging to the age group 1-5 years).

DISCUSSION

Although it includes only 100 cases of bacterial meningitis, compared with multicenter studies our study brings microbiologically documented data sufficient to support the epidemiological features in our geographic area, taking into account that the Iasi Infectious Diseases Hospital serves patients from most districts of North-Eastern Romania. *S. pneumoniae* was the most common cause of bacterial meningitis in children (8%), followed by *N. meningitidis* (6%) and *H. influenzae* (4%).

As in previous studies, the distribution of etiologies was age-dependent. *S. pneumoniae* was the most frequently isolated pathogen in children <1 year, with a peak of incidence in children 4-6 months, while N. meningitidis was the most common pathogen in older children. Mortality rate (5%) was lower than that reported in other industrialized countries (9.2%). Mortality rates associated with *N. meningitidis* and *S. pneumoniae* were 3% and 2%, respectively, lower than those reported in recent studies (7, 8).

The high frequency of *S. pneumoniae* strains with diminished susceptibility to penicillin (53.4% of isolates), supports the use of vancomycin associated with a third

generation cephalosporin (9, 10).

CONCLUSIONS

Bacterial meningitis remains an important public health issue, not just when it occurs in epidemics, but mostly because of its complications and high mortality. The low mortality rate in our hospital was due to an early CSF examination even in children with subtle signs of meningitis.

Bacterial meningitis should be considered in any case of acute fever in infants and children since the clinical picture in young children is less specific.

The high frequency of *S. pneumoniae* strains with diminished susceptibility to penicillin (53.4%) is an alarm signal that recommends the use of a third-generation cephalosporin or vancomycin as first-line therapy.

A good knowledge of the epidemiology of bacterial meningitis in children may serve as a guide for empirical antibiotic treatment, and also justifies the introduction of new conjugate vaccines into national vaccination scheme.

THE CENTRAL ROLE OF THE NON ALCOHOLIC FATTY LIVER DISEASE IN METABOLIC SYNDROME (Abstract): Non-alcoholic fatty liver disease (NAFLD) covers a spectrum of liver disease from steatosis to non-alcoholic steatohepatitis (NASH) and cirrhosis. Most NAFLD patients are hyperinsulinaemic and more insulin resistant compared with non-steatotic healthy subjects, and there is a near universal association between NAFLD and insulinresistance (IR) irrespective of obesity. The metabolic syndrome (MS) is highly prevalent in the general adult population (approximatively 22%) and it carries an increased cardiovascular morbidity and mortality. Pathophysiologic considerations, clinical associations, and laboratory investigations support that IR and hyperinsulinaemia have a central role in pathogenesis of both MS and NAFLD. The fatty liver is resistant to the action of insulin to suppress hepatic glucose production, which results in hyperglycaemia and, further, in hyperinsulinemia. The MS is associated with maldistribution of body fat, increased free fatty acids (FFAs) and IR, leading to type 2 diabetes, hypertension, dyslipidemia. Visceral fat is an important clinical marker of metabolic cardiovascular risk and a marker of IR in multiple tissues, independent of body mass index (BMI). NAFLD and atherosclerosis share common molecular mediators and NAFLD itself might play an early role in the development and progression of atherosclerosis. These data suggest that NAFLD should be considered part of a multi-organ system derangement in insulin sensitivity, and help explain why NAFLD is so closely linked with diabetes, MS and is an important risk factor for coronary heart disease. NAFLD may be the hepatic manifestation of the MS and raises the possibility that it may play an early role in the etiology of MS. **Key words:** NON-ALCOHOLIC FATTY LIVER DISEASE, INSULIN RESISTANCE, METABOLIC SYNDROME

Non-alcoholic fatty liver disease (NAFLD) has become an important public health problem because of its high prevalence, potential progression to severe liver disease and association with cardiometabolic abnormalities, including diabetes, the metabolic syndrome and coronary heart disease (CHD) (1, 2). Obesity is an important risk factor for NAFLD, and the prevalence of NAFLD is linearly associated with body mass index (BMI) (3). The mechanism responsible for the link between obesity and its metabolic complications involves insulin resistance (IR), which is a common feature of obesity and NAFLD, and is an important risk factor for

cardio-metabolic disease (4). Patients with NAFLD might be at greater risk for CVD than those without NAFLD; however, the putative increased CVD risk in patients with NAFLD might reflect the coexistence of underlying MS risk factors or, alternatively, NAFLD itself might confer a CVD risk above and beyond its association with the individual components of the MS (3, 5).

METABOLIC SYNDROME (MS)

MS is a clustering of risk factors (abdominal obesity, atherogenic dyslipidaemia, hypertension, elevated plasma glucose, a pro-thrombotic state and a pro-inflammatory state) that greatly increases an individual's probability for developing atherosclerotic cardiovascular disease, type 2 diabetes mellitus and chronic kidney disease (3, 5). According to the new definition (IDF and AHA 2009), people with any three of the following five criteria are considered to have MS: increased waist circumference (with ethnicity specific values); high triglycerides (≥150 mg/dl); reduced HDL cholesterol (<40 mg/dl for males and <50 mg/dl for females); elevated blood pressure (systolic ≥130 mm Hg and/or diastolic ≥ 85 mm Hg); increased fasting glucose ≥ 100 mg/dl.

The MS is highly prevalent in the general adult population (approximately 22%), with differences in relation to race, gender, and age (6). It carries an increased cardiovascular morbidity and mortality - they are twice as likely to die from and three times as likely to have a heart attack or stroke compared with people without the syndrome, which makes an early and correct assessment mandatory. The prevalence of the metabolic syndrome is very high in type 2 diabetes patients, in whom it influences the risk of chronic complications (1, 6)..

NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD)

NAFLD covers a spectrum of liver disease from steatosis to non-alcoholic steatohepatitis (NASH) and cirrhosis. According to the American Association for the Study of Liver Diseases, NAFLD is defined as fat accumulation in the liver exceeding 5% to 10% by weight (5, 6). Steatosis attributable to NAFLD is typically macrovesicular rather than microvesicular (4). Alcohol consumption should not exceed 20 g/day and viral (hepatitis B and C), toxic, autoimmune (clearly elevated antinuclear and anti-smooth muscle antibodies), and other causes of steatosis (Wilson disease, hypobetalipoproteinemia) should be excluded (7, 8).

NAFLD affects approximately 15-25% of the general population in various countries, and its prevalence increases steadily to 70–90% in obese or type 2 diabetic patients. NAFLD is currently the most common cause of abnormal liver function tests. Liver enzyme levels do not reliably correlate with liver histology, the full range of disease may be seen in patients who have normal transaminase levels (normal values being present in up to 78% of patients at any time) (4, 8). When elevated, the increase is mild, often restricted to ALAT, with an ASAT/ALAT ratio usually less than 1 (4, 8).

Why Is Liver Fat Related to Components of the Metabolic Syndrome?

Pathophysiologic considerations, clinical associations, and laboratory investigations support that IR and hyperinsulinaemia have a central role in pathogenesis of both MS and NAFLD (6). Even in nondiabetic individuals a fatty liver has been associated with causes of insulin resistance such as obesity and with consequences of insulin

resistance such as hypertriglyceridemia and hyperinsulinemia (9).

Although the epidemic of obesity has been accompanied by an increase in the prevalence of the MS, not all obese develops the syndrome and even lean individuals can be insulin resistant. The reason why some individuals are insulin resistant whereas other equally obese are not has long been unresolved. The development of fatty liver was associated with an increase in BMI even of 1 kg/m2 (around 2-3 kg), suggesting that relatively small changes in body weight may exert significant metabolic effects. Waist circumference is a better predictor of the risk of CVD than obesity and is associated with NAFLD as determined using computed tomography, liver biopsy or ultrasound techniques (10, 11, 12). Although the prevalence of NAFLD is higher in obese population, the liver fat is highly significantly and linearly correlated with all components of the metabolic syndrome independent of obesity (13).

Both lean and obese insulin resistant individuals have an excess of fat in the liver. Most NAFLD patients are hyperinsulinaemic and more insulin resistant compared with non-steatotic healthy subjects, and there is a near universal association between NAFLD and IR irrespective of obesity (3, 5). IR is a recognized risk factor for CVD, and plays a pivotal role in the development of poor clinical outcomes in NAFLD patients (5, 6). IR may be defined as a condition in which higher than normal insulin concentrations are needed to achieve normal metabolic responses or normal insulin concentrations fail to achieve a normal metabolic response (7, 14). Fasting serum insulin correlates closely with liver fat content independent of age, gender and BMI. The fatty liver is resistant to the action of insulin to suppress hepatic glucose production, which results in hyperglycaemia and, further, in hyperinsulinemia (9, 13, 15). ALAT levels correlated significantly with fasting insulin levels, suggesting that hyperinsulinaemia is an important contributor to the development of fatty liver, more crucial to the pathogenesis than anthropomorphic data, blood glucose or serum lipids (13).

The amount of intra-hepatic triglycerides (IHTG) in obese persons without diabetes is directly correlated with impaired insulin action in liver (suppression of glucose production), skeletal muscle (stimulation of glucose uptake) and adipose tissue (suppression of lipolysis), independent of percent body fat and intra-abdominal adipose tissue (IAAT) volume (16). IHTG content is a marker of insulin sensitivity in multiple tissues, independent of BMI. These results suggest that NAFLD should be considered part of a multi-organ system derangement in insulin sensitivity, and help explain why NAFLD is so closely linked with diabetes and the metabolic syndrome and is an important risk factor for coronary heart disease (1, 17).

Thus, NAFLD in its more advanced forms might act as a stimulus for further increased whole-body insulin resistance and dyslipidemia, leading to accelerated atherosclerosis. This hypothesis is also partly validated by few prospective studies demonstrating that raised liver enzymes independently predict the development of the metabolic syndrome (18, 19). So, we can say that NAFLD is an under recognized manifestation of the metabolic syndrome (15).

The role of adipose tissue - ectopic fat. Visceral (intra-abdominal) fat has attracted much interest both as a marker and an inducer of many of the metabolic abnormali-

ties associated with obesity. Abdominal circumference, surrogate marker of visceral fat, is an easily available clinical measurement of both CV risk and type 2 diabetes risks in obesity, being a good predictor of IR, dyslipidemia, low-grade inflammation (7, 8, 11). Excess of intra-abdominal fat in particular may be a key determinant in the pathogenesis of NAFLD, because of its strong association with IR and a source of free fatty acids (FFAs) (7, 20).

The MS is associated with maldistribution of body fat, increased FFAs and IR, leading to type 2 diabetes, hypertension, dyslipidemia and hypercoagulability (11). The role of ectopic fat depots, including the visceral depot, is to "spill-over" the lipids when the subcutaneous sites become insufficient (12, 20). The fact that the portal vein drains the visceral fat makes the liver an important target for the released adipokines. But, visceral adipose cells have an increased lipolytic rate and respond poorly to the anti-lipolytic effect of insulin. Visceral fat is a marker of ectopic fat and an important clinical marker of metabolic CV risk (11). The effect of IR may be mediated by increased portal FFAs, deacreased adiponectin, by cytokines and chemokines, which may exert local effects, as well as contribute to overall systemic release. Obesity with excess visceral fat is associated with reduced adiponectin, whereas obese persons with normal visceral fat have normal adiponectin levels (12).

Role of Adipose Tissue Inflammation. Chronic inflammation is frequently associated with the MS and the main inflammatory mediators are adipocytokines and FFAs. Pro-inflammatory cytokines that have been associated with MS include CRP, TNF-a, IL-6 and others and they result in more insulin resistance and lipolysis of adipose tissue triglyceride stores, in enhanced hepatic glucose and VLDL production. The increased secretion of TNF-α and other pro-inflammatory cytokines by adipocytes and infiltrating macrophages is thought to lead to chronic systemic inflammation as well as obesity-linked insulin resistance (21).

Elevated concentrations of circulating TNF-α have been documented in NAFLD patients and also its implications in the manifestation of fatty liver disease (21); is increased in obese and diabetic individuals, while weight loss decreases its levels. TNF-α inhibit lipoprotein lipase, stimulates hormone-sensitive lipase and induces uncoupling protein expression, down regulates insulin-stimulated glucose uptake via effects on GLUT-4, insulin receptor autophosphorylation and IRS-1 expression. TNF-α decreases the production and secretion of leptin by adipocytes (12, 21).

IL-6 seems particularly abundant in the visceral fat and chronically elevated IL-6 induces IR in both the liver and the adipose cells (11). IL-6 has pro-inflammatory properties and causes activation of Kupffer cells resulting in fibrogenesis; it also enhances hepatic C-reactive protein synthesis. In paracrine fashion, it decreases adiponectin secretion from the surrounding adipocytes, inhibits lipoprotein lipase (LPL) on endothelial cells and activates lipolysis (12).

TNF-α and IL-6 also induce development of hypertension (7, 21). Individuals with MS have significantly higher rate of sodium and water reabsorption at the proximal tubular level (7, 22). Insulin promotes endothelin-1 (ET-1) production, as well as ET-1 action in vascular smooth muscle cells, causing vasoconstriction and increased smooth muscle cells proliferation (7, 23, 24).

LIVER FAT – AN ATHEROGENIC CONDITION ASSOCIATED WITH INCREASED CARDIOVASCULAR RISK

Essential hypertension is considered an insulin resistant state and approximatively 50% of patients with arterial hypertension are reported to be insulin resistant and hyperinsulinemic. These metabolic abnormalities also seem to be involved in the pathogenesis of the complications of hypertension, both in obese and non-obese patients (15, 22). NAFLD and atherosclerosis share common molecular mediators and NAFLD itself might play an early role in the development and progression of atherosclerosis. The biological mechanisms by which NAFLD contributes to higher risk of CVD, independent of other prognostic factors, are not fully understood. It is possible that NAFLD, in its more advanced forms, acts as a stimulus for further increased whole-body IR and dyslipidaemia, leading to accelerated atherosclerosis (10, 24).

Recent studies clearly documented that NAFLD patients have significantly greater carotid artery intima-media thickness (IMT) than control subjects, a reliable index of subclinical atherosclerosis (25, 26). Other small studies showed that NAFLD patients have a significant decrease in endothelium-dependent vasodilatation and this decrease was significantly associated with the histological severity of NAFLD (1, 18). Villanova *et al*. (17-19) reported that brachial artery endothelial flow-mediated vasodilatation was decreased in non-diabetic subjects with NAFLD compared with control subjects. The severity of histopathological features in NAFLD is strongly associated with both early carotid atherosclerosis and the decrease of flow-mediated vasodilatation, independent of classical risk factors, IR and the presence of MS (8, 18). The 10-year probability of coronary events (Framingham equation) was moderately increased in these patients (17).

A possible atherogenic mechanism linking NAFLD and carotid IMT could be represented by increased oxidative stress and subclinical inflammation, which are thought to be causal factors in the progression from simple steatosis to more advanced forms of NAFLD (17, 18). Atherosclerosis is accelerated both directly by effects of cytokines on endothelial cells and indirectly by cytokine effects on the liver, causing increased production of CRP and related factors (27, 28). CRP induces endothelial cell adhesion molecules expression (27), inhibits nitric oxide synthesis, increases plasminogen activator inhibitor (PAI)-1 expression (28), and leads to endothelial dysfunction (21, 28). The concentrations of plasma adiponectin (cytokine of adipose tissue with antiatherogenic properties) are decreased in patients with NAFLD, compared with control subjects. This decrease is associated with the histological severity of NAFLD independent of IR and MS components (4, 10, 29); decreased adiponectin concentrations predict the incidence of CVD and MS in large prospective studies (4, 29) and appear to play a key role in the development and progression of NAFLD.

These strongly support the notion that NAFLD may be the hepatic manifestation of the MS (2). Currently, the importance of NAFLD and its relationship with the MS is increasingly recognized. However, the putative increased CVD risk in patients with NAFLD might reflect the coexistence of underlying MS risk factors or, alternatively, NAFLD itself might confer a CVD risk above and beyond the one associated with the individual components of the MS (11, 12).

Liver Fat Predicts the Metabolic Syndrome and Type 2 Diabetes. The evidences of the fact that NAFLD is a feature of the MS are on growing. Liver markers have been shown to be associated with MS variables in large samples of the general population. ALAT significantly predicts the incidence of MS and type 2 diabetes, associations that were maintained after adjustment for a large number of risk factors (including direct measures of insulin sensitivity and insulin secretion). This finding raises the possibility that NAFLD may play an early role in the etiology of MS (12, 30). First, these markers are known to be significantly correlated with increased hepatic fat content and it has been demonstrated that hepatic fat content is associated with IR independent of body weight (9). In particular, hepatic fat was associated with defects in the suppression of endogenous glucose production by insulin (9, 19); this could explain why ALAT values and ASAT/ALAT ratio predicted the onset of fasting hyperglycaemia (19).

The role of steatosis, estimated using liver enzymes, in the prediction of type 2 diabetes has been examined in 12 prospective studies. Elevated liver enzymes predicted type 2 diabetes independent of obesity. In a Swedish study of 54-year-old men, serum ALAT concentrations predicted a 3.9-fold increase in the risk of type 2 diabetes, which remained significant after adjusting for BMI (13).

CONCLUSIONS

Regardless of the origins of the metabolic syndrome and despite the fact that the pathogenesis of the fatty liver is poorly understood, the liver is responsible for production of many CV risk factors. Increased fat accumulation in the liver is a marker of hepatic IR and closely correlates with all components of the metabolic syndrome, independent of obesity. Adipose tissue inflammation and a fatty liver seem to coexist, but the direction of causality, is unclear. Epidemiological data have shown the fatty liver predict, independent of other factors, the MS, type 2 diabetes, and CVD.

STUDY ON THE ASSOCIATION OF IMAGING AND CLINICAL ANATOMIC DATA IN THE PREDICTION OF DIFFICULT INTUBATION (Abstract). Difficult intubation is a serious challenge for emergency doctors and anesthesiologists. **Aim:** This study was aimed at investigating the effectiveness of imaging methods combined with clinical anatomic data in predicting difficult intubation by developing a score as thorough and easy to use as possible. **Material and methods:** This prospective study was carried out on a series of 121 patients (51 males and 70 females), aged between 18 and 85 years (mean age 45.5 years) in the interval September 2010 0 June 2011. The patients, scheduled for various surgical interventions requiring general anesthesia by oral tracheal intubation, were randomly selected and gave a written consent. Children and pregnant women were excluded. The criteria for clinical anatomic assessment and cerebral and cervical imaging methods were used in all patients. By corroborating these data, a difficult intubation prediction score, named OMLET, was developed. It included 5 parameters: obesity (IMC), Mallampati score (modified), position of the larynx as to the spine, cervicothoracic angle (CTA), and head extension (DTM). Each variable was attributed 0 or 2 points, the highest score being 10 points, the obtained score being directly proportional with the expected difficulty during oral tracheal intubation. **Results:** Of the 121 patients, 9 were difficult cases, the incidence of difficult intubation being 7.43%. The Cormack-Lehane score predicted a difficult intubation in 11 of the 121 cases (sensitivity 77.78%, specificity 96.43%), while the OMLET score predicted 6 of the 9 difficult intubations (sensitivity of 66.67%, specificity of 95.43%. positive predictive value 54.55%, and negative predictive value 97.27%). **Conclusions:** The OMLET score proved effective in predicting difficult intubation expressed in its high specificity and sensitivity, and could be used especially in patients with conditions of the cephalic extremity and neck inevitably requiring before surgery investigation of these areas.

Căile respiratorii care implică intubația dificilă (ID) în situațiile de urgență reprezintă cea mai importantă provocare pentru medicii urgentişti şi anestezişti. Incapacitatea de a controla permeabilitatea căilor respiratorii şi a ventila pacientul în mod eficient (SpO2< 90%) poate duce la complicații grave care au un impact imediat asupra calității vieții sau chiar la decesul acestuia prin hipoxie cerebrală.

Societatea Americană de Anestezie (ASA) defineşte ID ca fiind incapacitatea unui anestezist instruit de a insera sonda de intubație în trahee prin laringoscopie con-

venţională, necesitând mai mult de 3 tentative de intubaţie orotraheală (IOT) şi/sau în mai mult de 10 minute (1). IOT dificilă neanticipată este principala cauză a morbidităţii şi mortalităţii în anestezia pacienţilor (1).

Scopul studiului este investigarea eficienţei metodelor imagistice (IRM) combinate cu datele anatomo-clinice în predicţia ID. Având în vedere coroborarea datelor imagistice cu elementele anatomo-clinice ne-am propus să stabilim un scor care să fie cât mai complet şi cât mai uşor de aplicat la fiecare caz şi care să cuprindă elementele de evaluare în scopul depistării unei posibile situaţii de ID.

MATERIAL ŞI METODE

Studiul prospectiv a fost realizat după obţinerea consimţământului, în perioada septembrie 2010 –iunie 2011. Pacienţii au fost selecţionaţi aleator, fiind programaţi pentru diverse intervenţii chirurgicale sub anestezie generală (AG) cu intubaţie orotraheală (IOT); au fost excluşi copiii, având particularităţi anatomice specifice vârstei şi femeile gravide, datorită modificărilor particulare din timpul sarcinii. Atunci când un pacient a fost exclus din studiu, altul a fost ales aleator în locul lui. Lotul de pacienţi s-a evaluat prin criteriile anatomo-clinice (tab. I).

TABELUL I

Criterii de evaluare anatomo-clinica a pacientilor

Parametru	Metoda de evaluare
Test Mallampati (modificat) (2) (de vizualizare)	Clasa I: palatele dur, moale şi uvula; Clasa II: palatul dur, moale şi partial uvula; Clasa III: palatul dur şi baza uvulei; Clasa IV: numai palatul dur, cel moale mascat  Clasa 1 Clasa 2 Clasa 3 Clasa 4
IMC ($IMC = G/h^2$)	< 18,5 Subponderabilitate 30 – 34,99 Obezitate gr. I 18,5 – 24,99 Normoponderabilitate 35 – 39,99 Obezitate gr. II 25 – 29,99 Supraponderabilitate > 40 Obezitate morbidă
DTM (3)	Distanţa dintre cartilajul tiroidian şi menton pe linia mediană în extensia maximă a capului.
Scorul LEMON (4, 5)	***L***: Examen extern: traumatism facial, incisivi răsfiraţi, excesde par facial (mustăţi, barbă), macroglosie ***E***: Regula "3-3-2": deschiderea gurii (3 lăţimi de deget), distanţa hio-mentonieră (3 lăţimi de deget), distanţa tiro-mentonieră (2 lăţimi de deget). ***M***: Scor Mallampati > 3 ***O***: Obstrucţia căilor aeriene: traumatisme, epiglotită, abcese peritonsilare. ***N***: Mobilitatea gâtului.
Clasificarea Cormack-Lehane (6) (de vizualizare)	Grad I - întreaga apertură laringiană; Grad II - numai comisura posterioară a aperturii laringiene; Grad III - numai epiglota; Grad IV - exclusiv palatul dur. 1 2 3 4

Pacienții incluși în studiu au fost investigati RM, cerebral şi cervical, după protocoale cu secvențe sagitale T1- şi T2 - ponderate fără supresie de grăsime, secvența coronala SPAIR (cu supresie de grăsime) şi secvența T2-ponderată axială fără supresie de grăsime. Pe imagini s-au determinat unghiul cervico-toracal (UCT) şi localizarea laringelui față de vertebrele cervicale. UCT este unghiul dintre dreapta ce unește marginea posterioară a vârfului dintelui axisului cu marginea posterioara a platoului inferior C7 şi dreapta ce unește marginea posterioară a platoului T1 cu marginea posterioara a platoului inferior T4 (fig. 1)

Fig. 1. Unghiul cervico-toracic şi laringe localizat pe secvența IRM sagitală T2-ponderată fără supresie de grăsime.

TABELUL II

Formular scor OMLET

	Variabilă	**Descriere**	**0 pcte**	**2 pcte**
O	**O**bezitate	IMC = G/h^2	< 30	> 30
M	**M**allampati	Scor Mallampati	Clasa 1 Clasa 2	Clasa 3 Clasa 4
L	**L**aringe	Localizarea laringelui	< C_5	> C_5
E	**E**xtensia capului	DTM	> 6 cm	< 6 cm
T	Unghi **T**oraco-cervical	UCT	În intervalul (130°-165^0)	În afara intervalului (130°-165°)
TOTAL scor ”OMLET”				

Coroborând datele obținute din examenul preanestezic cu cele obținute imagistic, am introdus un scor de predicție a ID, pe care l-am numit scor OMLET, care a cuprins 5 parametri: obezitatea (IMC), scorul Mallampati (modificat), laringele localizat față de coloana cervicală, DTM şi UCT. Fiecarei variabile i-a fost atribuit un punctaj de 0 sau 2 puncte (tab. II). Scorul maxim posibil este de 10 puncte, valoarea acestuia fiind direct proporțională cu dificultatea aşteptată în timpul IOT.

Achizițiile de imagine au fost efectuate pe aparat de IRM Siemens Avanto 1.5T cu ajutorul unei antene periferice (Neck Coil), cu poziționarea pacienților în decubit dorsal şi fixarea extremității cefalice în poziție neutră.

Examenul preanestezic şi IOT a fost efectuat folosind laringoscop rigid tip MacIntosh cu lama curbă numărul 4 sau 5, sonda endotraheală adaptată sexului şi particularităților anatomice ale pacientului. În cazul ID s-a folosit laringoscopul cu fibră optică tip MacIntosh şi s-a recurs la algoritmul managementului căilor respira-

torii dificile stabilit de ASA.

Prelucrarea şi interpretarea informaţiilor s-a realizat folosind programul EpiInfo vers. 3.5.1. şi în Microsoft Office Excel 2000. În calculul distribuţiei variabilelor s-a ales un interval de incredere (CI) de 95%; ″p″ < 0.05 a fost considerat semnificativ statistic iar pentru obţinerea sensibilităţii şi specificităţii, valorilor predictive, pozitiv şi negativ, am apelat la tabelul de contingenţă 2x2.

REZULTATE

Lotul de 121 pacienţi a fost alcătuit din 51 (42,1%) bărbaţi şi 70 (57,9%) femei cu vârste între 18 - 85 ani şi media vârstei de aproximativ 45½ ani. S-au evaluat datele clinice, imagistice şi dificultatea întâmpinată în timpul intubaţţiei (tab. III).

TABELUL III

Caracteristici anatomo-clinice şi imagistice evidenţiate pentru lotul de pacienţi incluşi în studiu

Caracteristica ***N = 121***		n*	%	95% CI**
Sex	Masculin	51	42,1	33,2 – 51,5
	Feminin	70	57,9	48,5 – 66,8
IMC	< 18,5	6	5,1	1,9 – 10,8
	18,5 – 24,99	49	41,9	32,8 – 51,4
	25,0 – 29,99	51	43,6	34,4 – 53,1
	30,0 – 34,99	8	6,8	3,0 – 13,0
	35,0 – 39,99	2	1,7	0,2 – 6,0
	> 40	1	0,9	0,0 – 4,7
Mallampati	1	52	43,0	34,0 – 52,3
	2	49	40,5	31,7 – 49,8
	3	18	14,9	9,1 – 22,5
	4	2	1,7	0,2 – 5,8
LEMON	0	46	38,0	29,3 – 47,3
	1	22	18,2	11,8 – 26,2
	2	18	14,9	9,1 – 22,5
	3	13	10,7	5,8 – 17,7
	4	14	11,6	6,5 – 18,7
	5	3	2,5	0,5 – 7,1
	6	5	4,1	1,4 – 9,4
Unghiul cervico-toracal	În afară interval (130°-165°)	15	12,4	7,1 – 19,5
	În intervalul (130°-165°)	106	87,6	78,4 – 94,8
Localizarea laringelui	C_4	5	4,1	0,9 – 8,2
	C_5	70	57,9	48,5 – 66,8
	C_6	44	36,4	28,6 – 46,4
	C_7	2	1,7	0,2 – 5,8
Cormack - Lehane	1	49	40,5	31,7 – 49,8
	2	61	50,4	41,2 – 59,6
	3	9	7,4	3,5 – 13,7
	4	2	1,7	0,2 – 5,8
Intubaţie dificilă	Da	9	7,4	3,5 – 13,7
	Nu	112	92,6	86,3 – 96,5

* n - număr pacienţi
** - pentru valorile mai mici, de 10 proporţiile sunt orientative
*** CI - interval de confidenţialitate

În incercarea de a găsi valoarea de referință a UCT pentru ID s-a efectuat o corelație între acest unghi şi cele mai folosite criterii de evaluare în predicția ID (clasificarea Mallampati, scorul LEMON, Cormack-Lehane) (fig. 2).

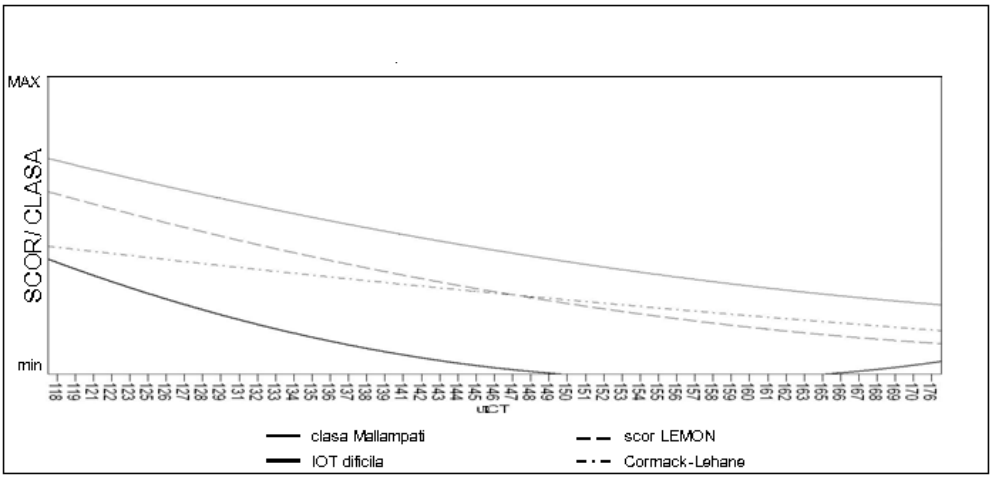

Fig. 2. Corelarea UCT cu cele mai importante scoruri/clasificări folosite în predicția ID.

Coreland UCT cu încadrarea pacienților în clasa Mallampati se observă că cele două variabile sunt în corelație inversă. Cu cât UCT este mai mare, cu atât clasa Mallampati (şi implicit dificultatea intubației) este mai mică. Considerand ca o ID devine posibilă şi probabilă la pacienții care au clasele Mallampati peste 2, vom putea afirma că pacienții cu un UCT mai mic de 140° pot fi candidați pentru o intubație posibil sau probabil dificilă.

De asemenea, a fost corelat UCT cu scorul LEMON. Ca şi în primul caz, corelarea grafică a fost de tip invers. Considerând că o intubație devine probabilă la valori ale scorului LEMON peste 3, putem afirma că pacienții care au un UCT mai mic sau egal cu 128° devin candidați pentru o posibilă sau probabilă ID (fig. 2).

Corelarea UCT cu scorul Cormack-Lehane descoperit în momentul laringoscopiei a fost de asemenea de tip invers, clasa Cormack-Lehane fiind cu atât mai mare cu cât UCT este mai mic (fig. 2).

Considerând că o intubație este posibil/probabil dificilă la un scor Cormack-Lehane peste 2, putem afirma că un pacient care are UCT sub 134° poate fi candidat pentru o intubație dificilă. Corelarea UCT cu dificultatea intubației întâlnită în timpul IOT descrie o curbă cu concavitatea superior şi traseu preponderent descendent, ceea ce evidențiază că pacientii cu valoarea UCT sub 132° pot fi candidați ai unei IOT dificile.

S-a remarcat faptul că, odată ce este depăşită valoarea de 165° a UCT, curba descrie o ascensiune, deci, şi o creştere a dificultății întâlnită în timpul intubației. Astfel, putem presupune că pacienții cu o valoare a UCT sub 130° pot fi încadrați în grupul de risc pentru o eventuală ID.

Datele clinice şi scorurile de evaluare a căilor respiratorii au fost utilizate pentru a obține sensibilitatea, specificitatea, valoarea predictivă pozitivă (VPP) şi negativă (VPN) a testelor (tab. IV).

TABELUL IV

Analiza comparativă a diverşilor factori sau sisteme de evaluare a intubaţiei dificile.

Sistem de evaluare	Se (%)	Sp (%)	VPP (%)	VPN (%)	RR	p
Obezitatea (IMC>30)	66,67	90,18	35,29	97,12	0,36	<0,05
Clasa Mallampati	66,67	85,71	27,27	96,97	0,28	<0,05
Localizarea laringelui (<C_5)	22,22	96,43	33,33	93,91	0,35	<0,05
Distanţa tiro-mentoniera (<6,5m)	66,67	91,96	40,00	97,17	0,41	<0,05
uCT (130-165)	55,56	90,18	31,25	96,19	0,32	<0,05
Clasa LEMON (>4)	66,67	98,21	75,00	97,35	0,77	<0,05
Cormack-Lehane	77,78	96,43	63,64	98,18	0,65	<0,05

Se = sensibilitatea; Sp = specificitatea; VPP = valoare predictivă pozitivă;
VPN = valoare predictivă negativă; RR = risc relativ

Dintre parametrii incluşi în scorul OMLET, DTM mai mică de 6,5 cm şi obezitatea (IMC > 30 kg/m^2) au avut cele mai mari puteri de predicţie a ID.

Scorul OMLET a prezis 6 din cele 9 intubaţii dificile, sensibilitatea testului fiind de 66,67%. Deşi 3 din totalul pacienţilor au avut un scor OMLET < 5, valoare considerată limită pentru IOT dificilă, ei au fost totuşi intubaţi greu (valoare fals-negativă). Din 112 pacienţi intubaţi normal/uşor, scorul OMLET a avut valori corespunzătoare unei IOT dificile (> 5) în 11 cazuri (valoare fals-pozitivă). Astfel, scorul OMLET a avut o specificitate de 95,54%, valoare predictivă pozitivă de 54,55% şi valoare predictivă negativă de 97,27% (tab. V).

TABELUL V

Valorile predictive ale scorului OMLET.

	Se (%)	Sp (%)	VPP (%)	VPN (%)	RR	p
Scor OMLET	66,67	95,54	54,55	97,27	0,56	<0,05

Se = sensibilitatea; Sp = specificitatea; VPP = valoare predictivă pozitivă;
VPN = valoare predictivă negativă; RR = risc relativ

S-a remarcat că valoarea predictivă a scorului OMLET este cel puţin egală cu cea a fiecărei variabile componente, dar riscul relativ (RR) este mai mare decat oricare dintre acestea, acest scor fiind util în practica curentă.

CONCLUZII

În prezent nu există nici un test care să prezică de unul singur probabilitatea unei intubaţii dificile cu o sensibilitate şi o specificitate suficient de mari, de aceea este necesară folosirea unui set complex de teste, diverse algoritme pentru evaluarea preintervenţională cu scopul de a prezice o intubaţie dificilă şi în acelaşi timp medicul urgentist sau anestezist trebuie să fie pregătit şi să stăpânească tehnicile de management a căii respiratorii dificile în cazul apariţiei unei astfel de situaţii neanticipate. Respectarea strategiilor definite şi algoritmilor pot rezolva cele mai multe probleme

în managementul căii respiratorii dificile, permițând intubarea cu succes la majoritatea pacienților cu căi respiratorii dificile. Atunci când gestionarea căilor respiratorii eşuează, s-a inclus un algoritm de gestionare a căilor respiratorii dificile care include dispozitive ce permit intubarea traheală sub control vizual direct, dar şi acestea implică preț de cost ridicat.

Mergând pe principiul că daca anticipăm o ID, aceasta poate să nu mai fie dificilă, fiind mai uşor să previi o anumită situație critică decât să o tratezi, anamneza, examenul clinic şi imagistic al pacientului rămân etape esențiale. În acest sens, prin elaborarea unui scor de predicție a ID folosind şi măsurători imagistice contribuie la identificarea ID la pacienții suspicionați. Comparativ cu factorii predictivi anatomo-clinci, metodele imagistice deşi nu sunt de rutină şi universal aplicabile, utilizarea lor s-a dovedit a fi potrivită pentru predicția de ID. Tehnicile imagistice imagistice – CT, IRM pot face măsuratori cu precizie, pot evidenția patologii asociate ale extremității cefalice şi a regiunii cervicale, dar rămân metode scumpe, disponibile numai în spitalele mari.

Scorul de IOT dificilă propus de noi este suficient de amănunțit, prin datele imagistice oferindu-ne o cantitate mare de informații (unghiuri, localizări, raporturi ale structurilor anatomice, patologii asociate căilor respiratorii superioare şi a zonelor de vecinatate). Acest scor ar putea fi aplicat în special pacientilor cu patologii ale extremității cefalice şi gâtului ce necesită inevitabil investigarea acestor regiuni preintervențional (patologii tumorale, patologii vertebro-medulare).

NOUTĂȚI

VALOAREA PREDICTIVĂ A *homB* ÎN MANAGEMENTUL BOLILOR GASTROINTESTINALE

În acest studiu au fost investigaţi factorii de virulenţă ai *H. pylori* în special distribuţia genelor *cagA*, *homA* şi *homB* în cazul tulpinilor izolate de la pacienţi cu boli gastrointestinale din Iran. De asemenea, un alt obiectiv a fost stabilirea corelaţiilor dintre stadiul bolii şi fcatorii menţionaţi anterior. A fost extras, amplificat şi secvenţiat ADN-ul genomic de la 138 de tulpini de *H. pylori* izolate de la pacienţi cu tulburări dispeptice (35 pacienţi cu gastrită, 62 pacienţi cu ulcer peptic, 42 pacienţi cu cancer gastric). Prevalenţa pentru *cagA*, *homA* şi *homB* a fost 58%, 54%, şi respectiv 43%. De asemenea s-a remarcat o diferenţă semnificativă a prevalenţei factorilor investigaţi în funcţie de stadiul bolii. Frecvenţa *homB* a fost semnificativ mai crescută în cazul pacienţilor cu cancer gastric (78%) decât în cazul pacienţilor cu ulcer peptic (20%) sau a pacienţilor gastrită (43%). Prezenţa lui *homB* a fost asociată cu prezenţa *cag A*. Aceste date sugerează că evaluarea *homB* poate avea valoare predictivă mai mare pentru prezenţa tulpinilor virulente de *H.pylori* iar prezenţa acesteia influenţează severitatea simptomatologiei clinice (Abadi A.T, Rafiei A, Ajami A, Hosseini A, et all. *Helicobacter pylori homB* but not *cagA* is associated with gastric cancer in Iran. *J ClinMicrobiol*. 2011: 3122-3126).

PAIN ASSESSMENT EFFECTIVENESS OF PAINKILLERS AT THE PATIENTS ADMITTED IN THE DEPARTMENT OF THE IASI "SF. SPIRIDON" COUNTY CLINICAL EMERGENCY HOSPITAL (Abstract): Pain represents a very common symptom and reason for doctor consultation in the patients coming to the emergency rooms. **Aim**: to identify the pathological conditions requiring painkillers in the emergency department and analyze the types of painkillers used in practice and their efficiency. **Material and methods**: patients who received painkillers in the Emergency Room (a total of 121 patients, 47.52% male) with a mean age of 57.57 were included in the study (January-June 2016). To assess pain at the time of admission and after treatment the World Health Organization analgesic scale principles were applied. The data were statistically analyzed by *Microsoft Excel 2010* and *SPSS 20.0* for Windows. **Results**: The most common diagnoses that had pain as the main symptom were physical trauma (30%) in various places, followed by abdominal pain syndrome (15 cases) and renal colic (12.4%). Depending on the diagnosis and experience of the emergency medicine doctor, the patients received analgesics such as paracetamol, fentanyl, and tramadol. Only 10% of the patients who received tramadol as initial treatment needed fentanyl to be added to reduce pain intensity (50-250 mcg). We established a positive correlation of $p< 0.01$ between the patients' degree of pain and their need to receive fentanyl. **Conclusions**: Regardless of etiology, the comparison of pain intensity at emergency department admission and discharge using the numeric pain intensity scale showed lower pain ratings at discharge. **Keywords**: PAIN, ACETAMINOPHEN, OPIOID, EMERGENCY DEPARTMENT.

According to the International Association for Study of Pain (IASP), pain is *"an unpleasant sensory and emotional experience associated with actual or potential tissue damage or described in terms of such damage"* (1). Romanian specialists in medical emergencies just like any other emergency room (ER) specialist in the world often face treating patients in pain. That is why the Canadian emergency departments regard the use of painkillers based on studies as a basic skill for the emergency physicians. Thus, protocols were developed based on Grading of Recommendations, Assessment, Development and Evaluation Methodology (GRADE)

seven PICO (Population, Intervention, Comparison, Outcomes) questions were developed, and subsequent scientific research for each question was conducted. Emergency Department analgesia protocols based on GRADE assessment have been suggested *to be used* by emergency physicians as guidelines, being considered as a *"book of analgesia in the emergency department"* (2).

All GRADE methodology has been used to develop an evidence-based approach to analgesia used in pre-hospital trauma. The group of specialists who have set it up recommends that all patients be candidates for analgesia irrespective of the type of transport and opioid medication to be taken in moderate and severe pain (3). Oligoanalgesia would also be caused by changes made by practitioners in the management of pre-hospital pain (4).

In Switzerland, specialists have conducted a study in view of developing and implementing educational interventions and a specific pain management in emergency services and to evaluate their effect on pain management the effect of the implementation of guidelines being evaluated in the same emergency department at admission and during emergency department stay. The study results showed an improvement in the handling and treatment of patients with pain, pain management, analgesia and patient comfort in Emergency Department following education program and guidelines implementation (5, 6).

MATERIAL AND METHODS

The study was conducted on 121 patients who were admitted to the Emergency Department (ED) of the Iaşi "Sf. Spiridon" County Clinical Emergency Hospital, between January-June 2016 and the main presenting symptom being pain of various causes.

The subjects that received one of the studied painkillers (paracetamol, fentanyl and tramadol) were asked to rate the intensity of their pain at admission and at 15, 30, and 60 minutes during treatment on a simple numeric scale (SNS) where 1 = no pain and 10 = high intensity pain (7, 8). The patients received one of the following 3 painkillers: paracetamol, tramadol and fentanyl. Seven work hypotheses were developed and the benefit of treating pain with the three painkillers was statistically assessed.

The data were statistically analyzed using *Microsoft Excel 2010* and *SPSS v.20.0* (9). The benefit of the study painkillers is expressed in a reduction of pain at fixed time intervals following their administration (what percentage of the baseline score is the difference between the baseline score and the final score, or the score measured sometime after administration).

RESULTS

The study group including 121 patients was homogenous. The mean age of the 121 study patients was 57.57 years, and the male patients being the majority (55.37%) with a male/female ratio of 1.2/1. Most patients came from the rural area (60.33%), the rural/urban ratio being 1.5/1.

Hypothesis 1a. Does age influence the benefit of painkillers in the treatment of pain? The benefit of painkillers following pain treatment was analyzed in two age groups: under and over 50 years old (tab. I). The benefit shows a tendency to decrease with age, with the highest benefit recorded in the young patients.

Hypothesis 1b. Does gender influence the benefit of painkillers in the treatment of pain?

The average benefit was around 28%

with insignificant male/female differences.

Hypothesis 1c. Does urban/rural residence influence the benefit of painkillers in the treatment of pain? No significant differences between rural and urban patients were found.

Hypothesis 2a. Do higher than normal ASAT and ALAT levels influence the benefit of painkillers in the treatment of pain? The benefit rate was lower (19.58%) in patients with ALAT and ASAT levels higher than 30 IU (tab. II).

Hypothesis 2b. Do higher than normal ALAT and ASAT levels influence the gender- related benefit of painkillers (tab. III).

TABLE I

Age-related benefit of painkillers at the end of pain treatment

Age group	Cases No. / %	Total score		Benefit (%)	Benefit / case (%)
		before treatment	after treatment		
Under 50	36.74%	162	116	28.40	0.68
Over 50	63.16%	284	204	28.17	0.39
Total	100.00	446	320	28.25	0.25

TABLE II

The benefit of painkillers according to ALAT and ASAT levels

Cases / Score	ASAT and ALAT	
	> 30 IU	< 30 IU
No. of cases	36	58
Total score before treatment	143	224
Total score after treatment	115	146
Treatment benefit (%)	19.58	34.82

TABLE III

The benefit rate of painkillers in women and men with ALAT and ASAT levels higher than 30 IU

Patient gender	No. of cases	Total score		Benefit (%)	Benefit %/case
		before treatment	after treatment		
Women	16	63	50	20.63	1.29
Men	22	87	68	21.84	0.99
Total	38	150	118	21.33	0.56

Hypothesis 3. Does the diagnosis responsible for pain influence the benefit rate of the treatment with painkillers? The main diagnosis was multiple contusions – 31% of cases, followed by renal colic and abdominal pain syndrome - 13% (fig. 1). The highest benefit/case (2.7%) was recorded in acute limb ischemia, followed by renal colic and neuralgia, of approximately 2.5%. The average benefit/case was of 0.25% (tab. IV).

TABLE IV
Benefit according to diagnosis

Diagnosis	% of cases	Total score		Benefit (%)	Benefit case (%)
		before treatment	after treatment		
Multiple contusions	31%	146	104	28.77	0.78
Abdominal pain syndrome	13%	59	45	23.73	1.58
Renal colic	13%	58	36	37.93	2.53
Acute limb ischemia	12%	53	33	37.74	2.70
Neuralgia	11%	52	35	32.69	2.51
Isolated fractures and dislocations	20%	78	67	14.10	0.71
Total	100.00	446	320	28.25	0.25

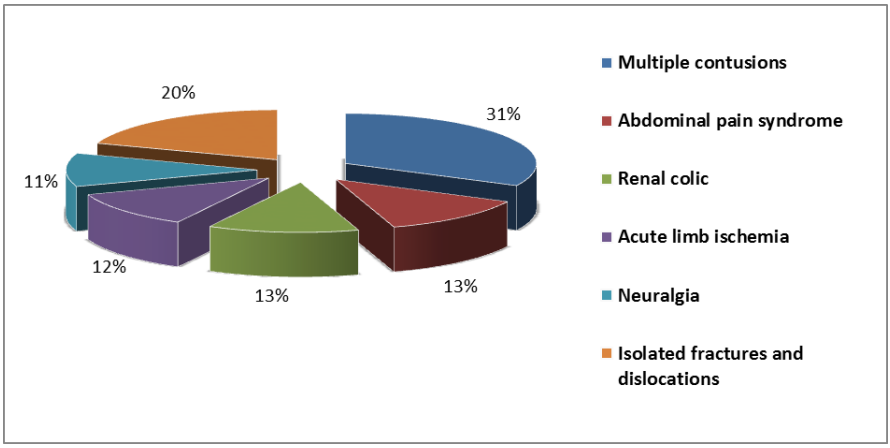

Fig. 1. The percentage of the diagnoses causing pain

Hypothesis 4. Does the heart rate influence the self-assessment of pain? The pain score obtained by the patients on the SNS was not influenced by their heart rate.

Hypothesis 5. Do the cases with concomitant conditions/diseases have a higher benefit rate in the case of pain treatment with painkillers? Half of the studied cases had concomitant conditions. Following pain treatment, the patients received approximately the same benefit rate as those who did not have concomitant conditions.

Hypothesis 6. Are the benefits of painkillers higher in the treatment of pain in patients with associated diseases? Adverse reactions were present in 7.44% of patients and the treatment benefit rates were of about 29% in the patients with or without adverse reactions. The most common adverse reactions were nausea and vomiting.

Hypothesis 7a. How does the concomitant medication use influence the benefit rate of pain treatment with painkillers? The benefit rate of treating pain with painkillers is higher in patients without concomitant medications the difference being of almost 5%.

Hypothesis 7b. Was pain treatment benefit rate influenced by the concomitant medication for preventing the adverse reactions to painkillers? (tab. V).

TABLE V
The influence of concomitant medication against adverse reactions

Medication	No. of cases	Total of pain score		Benefit (%)
		before treatment	after treatment	
Total patients	100	392	283	27.81
With concomitant medication for preventing the adverse reactions to painkillers	62	247	200	19.03
Without concomitant medication for preventing the adverse reactions to painkillers	38	145	83	42.76

DISCUSSION

All patients admitted in the emergency receiving unit are monitored hemodynamically and respiratory by recording the arterial pressure, heart rate and oxygen saturation. Analyzing these values, an increased incidence of those with high heart rate has been noticed (pulse > 100 / min) possibly because the pain causes a physiological stress response that includes the increase of the ventricular rate, respiratory frequency, which implies a more pronounced demand for oxygen and nutrition in the vital organs (10).

Knowing that both paracetamol and opioids are metabolized to the greatest extent in the liver cell, prior to their dosing, liver cytolysis enzymes (ALAT and ASAT aminotransferases) were harvested, but the intensity of pain when the patient was admitted in the emergency care did not allow us to wait for the results of these analyses to initiate appropriate treatment. The mean of ASAT and ALAT values was 30 IU; over 20% of those questioned having elevated transaminases, values that helped directing the subsequent antalgic treatment according to the recommendations of gastroenterology specialists.

A study performed in United States of America, in May 2010, showed that it is recommended to avoid using opioids in patients with impaired liver function because they favor portal systemic encephalopathy as fentanyl and tramadol are mainly metabolized by the liver (11). However, Chadock *et al.* (12) suggest the short-term use of opioids as a solution in such patients with acute pain associated with an underlying disease (other than liver etiology). Being familiar with these recommendations, in our study we administered only fentanyl in patients with liver cirrhosis considering as beneficial both the intravenous hydration and taking antiemetics.

All those diagnosed with acute myocardial ischemia, acute myocardial infarction, ulceration and multiple localization had maximum pain intensity (SNS = 9-10) of all the patients under study and inquired on arrival at our unit. 46.5% of those diagnosed with renal colic, and 50% of the subjects with dislocations and fractures isolated in a member segment had agonizing pain with a score at the top of the scale (SNS = 9-10). In our study, we used paracetamol as a first-line drug for those with moderate and weak pain. If some of those included in the study after treatment with acetaminophen scored the pain significantly lower, others had to add an opioid analgesic (tramadol or fentanyl). Combining the data obtained with the literature shows that acetaminophen has proved its maximum efficacy in moderate and weak pains. But a group of intensive care physicians in Istanbul have concluded that the analgesic

properties of paracetamol are equivalent to fentanyl in suction curettage procedures, concluding that more extensive studies are needed (13). Only 33% of the people with high intensity pain (SNS = 9-10) received tramadol as first-line drug after the medical check-up. Those with unbearable pain (renal colic, neuralgia, multiple fractures) did not benefit from the same treatment. We wonder why not all patients with unbearable pain have received tramadol to relieve pain on primacy? Opioids also have strong side effects (nausea, vomiting, dizziness, orthostatic hypotension) in addition to the powerful analgesic effect, which has made it possible to limit the use of tramadol in some of them. In some patients who received tramadol and paracetamol as an analgesic initiator, it was necessary to add another opioid more than 600 time stronger than morphine, fentanyl. The Pearson correlation was used to evaluate the efficacy of fentanyl treatment. Between the degree of pain of the patients and the need to receive fentanyl, the result obtained showed a strong statistically significant correlation between the most sensitive of 0.01 of the pain scale and the administration of fentanyl. If upon arrival in the emergency department 48% of those interviewed had a score (SNS = 9-10) and 47% respectively had a score (SNS = 7-8), only 9% left our department with a maximum score (SNS = 9). This score may not even reflect reality, with some patients adding an anxiety component in expressing pain (14).

A study performed in France, in 2010 showed that anxiety occurs in trauma patients as a pejorative factor of analgesia, the more anxious patients expressing a higher pain score and independent from other studied factors. This correlation has already been demonstrated in pediatrics, in patients with burns, dental pain or back pain (15).

The benefit of analgesic pain treatment can be noticed and summarizing the statistical data from this study can answer with yes or no to certain assumptions. The patients' age had a slight influence showing that the benefit of the established treatment was superior to those under 50. Only those with renal colic, neuralgia and painful abdominal syndrome benefitted the most of all the diagnoses stated whose main symptom was pain. Even if some subjects had associated comorbidities, there were no differences in the benefit of the treatment used compared to those without comorbidities.

As it is known from medical literature, some opioid drugs also have side effects, but our goal of treating pain has been reached without being influenced by side effects in some subjects.

There is a statistically insignificant difference in patients who have not received concomitantly other medication for the treatment of other associated comorbidities (27.81%) than those who received at least one drug for associated pathologies (24.07%), but this does not prevent us from treating both pain and prior pathologies specific to each patient. Even though our study shows that some patients who received treatment to avoid or treat side effects the benefits to analgesic treatment were lower compared to those who did not receive any medication. In the future, we should not neglect these reactions, which create additional discomfort to the recipient.

CONCLUSIONS

Our studies highlighted that the younger the patients, the higher the benefit rate of pain treatment with painkillers. ASAT and ALAT < 30 IU favor the outcomes of pain treatment. With the acute limb ischemia,

renal colic and neuralgia as pain causes, the benefit rate of pain treatment with painkillers is higher than with other studied causes. Lack of treatment for concomitant conditions does not involve achieving better benefit rates for the treatment of pain with painkillers. Patients without concomitant medication against adverse reactions had improved pain scores after treatment with painkillers. In only 10% of the patients who received tramadol and fentanyl as first-line treatment the pain, intensity scores forced us to use fentanyl dose titration, which proves that the opioids used in the study had a strong analgesic effect according to data in the medical literature. Over 60% of the study subjects required the association of a second analgesic in this case fentanyl or tramadol. Determining the effectiveness of pain management requires other hypotheses, better monitoring during pain treatment, pain assessment at some intervals after treatment, the use of different doses and in different combinations.

ARRHYTHMOGENIC EFFECTS OF ALCOHOL (Abstract): Acute or chronic excessive consumption of alcohol can cause cardiac arrhythmias, particularly supraventricular tachyarrhythmias. Experimental and clinical data show that chronic excessive alcohol ingestion has a destructive role on cardiac tissue, which significantly deteriorates the rhythm and contractile activity, manifested by the appearance of cardiac arrythmias and dilated cardiomyopathy. **Aim:** The aim of this study was to evaluate and analyze the ECG changes - disturbances of cardiac rhythm and conduction in patients after an acute or chronic excessive consumption of alcohol. **Material and methods:** The study included a number of 187 patients (184 males and 3 females). Each patient followed biochemical and hematological analysis as well as paraclinical investigation measurements. **Results:** The most common types of arrhythmia were permanent atrial fibrillation (61%). Paroxysmal atrial fibrillation and supraventricular extrasystoles were found in patients without significant echocardiographic deteriorations. These arrhythmias appeared after an alcohol abuse and paroxysmal atrial fibrillation was converted to normal sinus rhythm after a short period of abstinence or pharmacologic therapy administered. Ventricular arrhythmias (ventricular extrasystoles, non-sustained ventricular tachycardia-4.7%, torsada de point-1.5%) were less frequent. Conduction disturbance (left bundle branch-LBBB 6.3%, right bundle branch-RBBB 10%) were found in patients who had a history of consuming >150 g/day of alcohol for >10 years, with dilated heart chambers and systolic ventricular function much more deteriorated (symptomatic stage of heart failure). **Conclusion:** Excessive alcohol consumption may lead to cardiac arrhythmias in patients with existing heart disease as well as in healthy individuals. **Key words:** ARRHYTHMIA, CONSUMPTION, ETHANOL.

Consumul exagerat acut sau cronic de alcool poate determina tulburări de ritm şi conducere atât la nivel atrial cât şi ventricular.

Efectul aritmogen al etanolului până în prezent nu este pe deplin elucidat, dar se presupune că există mai mulţi factori care contribuie la geneza aritmiilor cardiace condiţionate de etanol. Ettinger şi colab. în 1978 descriu "*Sindromul cardiac de sfârşit de săptămână"* (*Holiday heart syndrom*) constând în aritmii cardiace ce apar după un consum abuziv de alcool la sfârşit de săptămană (după week-end) incluzând atât aritmii supraventriculare cât şi ventriculare.

Se consideră că perturbările cardiovas-

culare întâlnite la consumatorii cronici de alcool şi în special tulburările de ritm şi conducere reprezintă o cauză din ce în ce mai importantă de morbiditate şi mortalitate.

Scopul acestui studiu a constat în evidenţierea şi analizarea modificărilor electrocardiografice - tulburările de ritm şi conducere la pacienţii internaţi după un consum exagerat acut sau cronic de etanol (1,2,3,4).

MATERIAL ŞI METODĂ

Studiul a fost efectuat pe un lot de 187 de pacienţi internaţi în Clinica I Medicală a Spitalului "Sfântul Spiridon" Iaşi în perioda 1996-2002.

În studiu au fost incluşi pacienţii diagnosticaţi cu cardiomiopatie alcoolică ce au solicitat internarea în mod repetat, precum şi cei care au fost internaţi pentru prima dată şi au confirmat prin anamneză că sunt consumatori de etanol. Au fost excluşi din studiu pacienţii care nu au recunoscut consumul de etanol în ciuda faptului că examenul obiectiv şi investigaţiile paraclinice au fost pozitive pentru cardiomiopatie alcoolică. Vârsta medie a pacienţilor cuprinşi în studiu a fost de 52 ± 8,5 ani, variind între 25 şi 79 ani, iar sexul masculin a predominat (184 bărbaţi şi 3 femei).

La fiecare pacient au fost efectuate o serie de teste biochimice şi hematologice precum şi ECG, radiografie toracică, ecocardiografie transtoracică, iar la unii pacienţi s-a făcut şi monitorizare Holter ECG 24 de ore. Pentru urmărirea modificărilor electrocardiografice respectiv tulburările de ritm şi conducere, electrocardiograma s-a înregistrat repetat, zilnic sau de mai multe ori pe zi.

Cu ajutorul ecocardiografiei au fost determinate diametrul cavităţilor cardiace atriale şi ventriculare, cinetica globală a ventriculului stâng, fracţia de scurtare şi fracţia de ejecţie a ventriculului stâng, grosimea pereţilor ventriculari, regurgitările valvulare semnificative hemodinamic.

REZULTATE

Studiul relevă predominanţa sexului masculin - 184 cazuri (98%), dar această diferenţă semnificativă se explică atât prin factorii socio-culturali, tradiţionali, cât şi prin reticenţa femeilor în a declara consumul de etanol. În ceea ce priveşte mediul de proveniență 64% din pacienţi (120) proveneau din mediul rural şi fară activitate profesională, iar restul de 36% (67 pacienţi) din mediul urban şi cu activitate profesională (tab. I).

Aritmiile cardiace întâlnite la lotul de bolnavi au fost destul de numeroase, atât cele supraventriculare cât şi ventriculare. Dintre aritmiile prezente la pacienţii investigaţi, fibrilaţia atrială a fost cea mai frecventă, atât sub formă paroxistică, persistentă şi mai ales permanentă (109 pacienţi - 61%), urmată de extrasistole atriale multifocale la 105 de cazuri (56%). Fibrilaţia atrială paroxistică şi persistentă au apărut în relaţie cu consumul unor cantităţi exagerate de etanol (tab. II).

Datele ecocardiografice obţinute la acest grup de pacienţi au relevat diametre crescute ale cavităţilor cardiace, predominant stângi, scădere marcată a fracţiei de ejecţie şi scurtare (30 ± 2,7%), insuficienţă mitrală semnificativă hemodinamic (67% din cazuri) (tab. III).

Markerii consumlui de etanol reprezentaţi de GGT şi VEM au avut valori medii de 83 ± 4,8 U/l respectiv 96 ± 2,5 γ^3. Nu au existat tulburări electrolitice asociate în procent semnificativ. Fibrilaţia atrială permanentă a fost prezentă la aproape toţi

pacienţii din studiu care au declarat consum peste 100 g alcool/zi, cu durată de > 5 ani. Tulburările de ritm şi conducere la nivel vetricular şi joncţional au fost prezente la un procent mai mic: extrasistole ventriculare monomorfe la 94 pacienţi (50%), tahicardii ventriculare nesusţinute la 9 pacienţi (4%), torsada vârfurilor la 3 pacienţi (1,5%), iar tulburările de conducere interventriculare sub formă de BRD la 19 pacienţi (10%), BRS la 11 pacienţi (6%) şi HBAS la 15 pacienţi (8%).

TABELUL II

Relaţia între tipul aritmiei cardiace şi durata consumului de etanol/ani la pacienţi cu consum >100 g/zi

Tipul aritmiei cardiace	**Durata consumului de etanol > 100 g/zi**			
	> 5 ani	**5-10 ani**	**> 10 ani**	Numărul pacienţilor
Extrasistole atriale multifocale	70 (37%)	9 (4,8%)		
Fibrilaţie atrială - paroxistică →	20 (10%)			
Fibrilaţie atrială - persistentă →	10 (5,3%)	9 (4,8%)		
Fibrilaţie atrială - permanentă →		27 (14%)	43 (23%)	
Extrasistole ventriculare	42 (22,5%)	36 (19%)	23 (12%)	
Tahicardie ventriculară nesusţinută	1 (0,5%)	3 (1,5 %)	5 (2,6%)	
Torsada vârfurilor	3 (1,3%)			
BRD		3 (1,5 %)	16 (8,5%)	
BRS		4 (2,1%)	7 (3,7%)	

TABELUL III

Corelaţia dintre aritmile cardiace şi diametrul telediastolic al ventriculului stâng determinat prin ecocardiografie transtoracică

Tipul aritmiei cardiace	Diametrul telediastolic al ventriculului stăng măsurată prin ecocardiografie transtoracică			
	55- 65 mm	**65-75mm**	**>75mm**	
Extrasistole atriale multifocale	63 (33,6%)	45 (24%)		Numărul pacienţilor
Fibrilaţie atrială - paroxistică →	20 (10%)			
Fibrilaţie atrială - persistentă →	10 (5,3%)	11 (7,4%)		
Fibrilaţie atrială - permanentă →	3 (1,5%)	27 (17 %)	38 (20%)	
Extrasistole ventriculare	32 (17 %)			
Tahicardie ventriculară nesusţinută		3 (1,5 %)	6 (3,2%)	
Torsada vârfurilor	3 (1,5 %)			
BRD		7 (3,7%)	12 (6,4%)	
BRS		3 (1,5 %)	9 (4,8%)	
HBAS	1 (0,5%)	5 (2,6%)	9 (4,8%)	

DISCUŢII

Din datele experimentale şi clinice rezultă că etanolul are rol distructiv asupra ţesuturilor cardiace, ceea ce perturbă semnificativ atât activitatea contractilă cât şi ritmicitatea, manifestate prin apariţia cardimiopatiei dilatative şi aritmiilor cardiace (3,4,5,6).

Koskinen şi colab., în 1987, atestă rolul consumului de alcool în geneza unor tulburări de ritm la nivel atrial la un grup de bolnavi cu vârsta între 35-65 de ani, şi debut al fibrilaţiei atriale în urma unui consum excesiv de alcool. În lotul nostru de studiu am observat că toţi pacienţii au prezentat unul sau mai multe tipuri de aritmii cardiace, fie supraventriculare, fie ventriculare, sub formă de tulburări de ritm sau conducere (6,7).

Fibrilaţia atrială a fost aritmia cea mai frecventă la cazurile investigate, instalată de cele mai multe ori după un consum exagerat de etanol, favorizând agravarea insuficienţei cardiace. Fibrilaţia atrială paroxistică care a fost redusă în ritm sinusal după oprirea alcoolului şi aplicarea terapiei medicamentoase a fost prezentă la pacienţii care au consumat alcool pe o periodă de timp < 5 ani, şi cu parametri ecocardiografici mai puţin alteraţi comparativ cu forma permanentă care a fost întâlnită la marea majoritate a pacienţilor care au consumat cantităţi mari şi timp îndelungat (> 150 g/zi şi > 10 ani). La acest ultim sublot datele ecocardiografice au relevat parametri mult alteraţi: cavităţile cardiace mult dilatate, funcţia contractilă globală mult redusă. Extrasistolele atriale multifocale au fost prezente mai ales la cei care au fost convertiţi în ritm sinusal.

Frecvenţa aritmiilor ventriculare în acest lot a fost mai mică, dar se constată o corelaţie directă între consumul de etanol şi apariţia lor. Trebuie menţionat faptul că instalarea unor aritmii ventriculare: extrasistole ventriculare polimorfe, tahicardia ventriculară nesusţinută, şi nu în ultimul rând torsada vârfurilor, întâlnită în lotul nostru au o semnificaţie severă şi potenţial letală. În ceea ce priveşte tulburările de conducere, acestea au fost întâlnite la cazurile care au consumat cantităţi exagerate de

alcool > 150 g/zi o durată lungă de timp (peste 10 ani).

CONCLUZII

Consumul de alcool poate produce instabilitate electrică a inimii şi se manifestă clinic prin palpitaţii (având drept suport aritmiile) şi agravarea insuficienţei cardiace.

Modificările electrocardiografice întâlnite la pacienţii cuprinşi în studiu au fost destul de variabile sub formă de tulburări de ritm şi de conducere, atât la nivel atrial cât şi ventricular, reversibile la sevraj şi terapie corespunzătoare.

Fibrilaţia atrială şi tulburările de conducere apar îndeosebi la cazurile la care durata consumului de alcool este prelungită şi în cantităti peste 150 g/zi.

CORELATIONS BETWEEN ANTHROPOMETRIC PARAMETERS AND CARDIO-VASCULAR RISK FACTORS RELATED TO LIFESTYLE IN A RURAL POPULATION. (Abstract) **Background and aims.** Prevention and reduction of cardio-vascular mortality are in relationship with understanding and being able to modify risk factors, among which overweight and obesity become the most significant. The aim of this paper is to define cardio-metabolic risk factors which are specific to the studied population, and also to find elements of lifestyle that lead to overweight. We targeted smoking, alcohol consumption, stress, physical exercise, income and educational level. **Material and methods.** We studied a sample of 172 subjects, representative for the population of Deleni, a rural community in Iaşi County; among these subjects, 67 were men, 105 were women, with an average age of 54. For each a chart was filled, containing demographic data, socio-economic status, personal and family medical history. We measured anthropometric parameters: weight (W), height (H), waist circumference (WC) and we calculated body mass index (BMI), waist-to-hip ratio (WHR), and waist-to-height ratio (WHtR). We performed interviews to fill in a food frequency questionnaire, the Perceived Stress Scale and the International Physical Activity Questionnaire. **Results.** In the lot studied, 44.2% are overweight and 18.6% are obese, the majority of these being women. Regarding WC, among normal weight, 52.4% have large WC (≥94cm for men and ≥80cm for women). Obesity markers positively correlate with increase in age and decrease in income (p=0.024), with low educational level, regular consumption of coffee (p=0.093), and negatively correlate with excessive alcohol consumption (p=0.049) and smoking (p=0.003). As expected, there is an inverse relationship between increased physical exercise and BMI (p=0.015) and a direct relationship between increased stress level and WC. **Conclusions.** Anthropometric parameters are sensible markers in evaluating the influence of lifestyle on cardio-metabolic risk. **Key words:** CARDIOVASCULAR RISK, LIFESTYLE RISK FACTORS, ANTHROPOMETRIC PARAMETERS

Stilul de viaţă modern are o mare influenţă asupra energiei utilizate *vs* energia stocată, printr-o evidentă disponibilitate de alimente cu densitate calorică crescută în contrast cu o viaţă tot mai sedentară. Supraponderea şi obezitatea sunt factori de risc majori pentru mortalitatea şi morbiditatea prin boli cardiovasculare, diabet zaharat de tip 2, cancere şi altele care duc la aproximativ 3 milioane de morţi in fiecare an (1).

Indicii antropometrici cum ar fi indicele de masa corporală (IMC) sau circumferinţa taliei (CA), raportul talie/şold (T/S) şi raportul talie/înălţime (T/I) sunt evaluaţi ca predictori ai prezenţei riscului cardiovascular individual sau într-o comunitate, rămânând controverse asupra celui mai bun indicator. În studii populationale, IMC este recomandat de Organizaţia Mondială a Sănătăţii (OMS) pentru a stabili severitatea bolii (2). În 2005, International Diabetes Federation (IDF) propune CA pentru definirea sindromului metabolic (3). IMC este folosit ca indicator al grăsimii totale, în timp ce CA, T/S şi T/I sunt consideraţi markeri surogat ai obezităţii centrale. Numeroase studii vor să ierarhizeze indicii de apreciere ai supraponderii şi obezităţii în relaţie cu creşterea riscului cardiovascular (4). Majoritate a factorilor de risc sunt modificabili prin schimbări ale stilului de viaţă. Nutriţia este principalul factor controlabil în prevenţia şi reducerea obezităţii, diabetului zaharat de tip 2 şi a sindromului metabolic. Evaluarea ei este însă foarte dificilă. Mesele conţin o varietate de alimente cu combinaţii complexe de nutrienţi care sunt interactivi sau sinergici (5). Chestionarele de frecvenţă alimentară sunt un mijloc de apreciere a dietelor uzuale în studii epidemiologice largi, de a clasifica populaţia studiată după consumurile alimentare pe parcursul anului şi de a genera recomandări pentru sănatate (6). Alături de dieta aterogenă şi sedentarism la creşterea riscului cardiovascular contribuie şi adicţia la fumat şi alcool şi stresul (7). Prima aproximare a predicţiei riscului pe evaluările din cabinet sunt esenţiale pentru a iniţia procesul de selecţie a pacienţilor vulnerabili pentru viitoare intervenţii sau teste adiţionale.

MATERIAL ŞI METODE

Suntem în desfăşurarea unui studiu transversal, pe un lot reprezentativ din populaţia comunei Deleni-Iaşi. Scopul studiului este de a defini factorii de risc cardiometabolic specifici acestei populaţii şi cauzele legate de stilul de viaţă care duc la creşterea obezităţii: alimentaţie, fumat, consumul de alcool, stres, efort fizic, starea materială şi nivel de educaţie. Avem un lot de 172 de participanţi, dintre care 67 bărbaţi (39%) şi 105 femei (61%), cu vârste între 21 şi 91 ani, media fiind de 54 ani (53,1 ani la bărbaţi şi 54,7 ani la femei). Toţi participanţii au semnat consimţământul informat înainte de intrarea în studiu. Pentru fiecare persoană s-a completat o fişă cu date demografice şi socio-economice: nivel de educaţie, ocupaţie, venituri, status marital, obiceiul de a fuma, boli antecedente sau prezente, istoric de boli familiale. S-au măsurat parametrii antropometrici: greutatea, înălţimea, circumferinţa abdominală, circumferinţa şoldului şi s-au calculat indicele de masă corporală (IMC), raportul talie/şold (T/S) şi raportul talie/înălţime (T/I). Înălţimea şi greutatea au fost obţinute cu echipamente şi tehnici standardizate. Măsurarea circumferinţei abdominale s-a realizat cu subiectul dezbrăcat, în poziţie verticală, la jumătatea distanţei dintre rebordul costal şi creasta iliacă, la sfârşitul expirului normal, utilizând o bandă gradată, neextensibilă. Indicele T/I se calculează împărţind circumferinţa abdominală la înălţime, considerându-se ca normal orice valoare <0,5 indiferent de sex. IMC se calculează împărţind greutatea la pătratul înălţimii: IMC = $G(kg)/I^2(m^2)$**.** S-a stabilit diagnosticul de supraponderе sau obezitate conform criteriilor OMS: IMC = 25-29,9kg/m^2 – supraponderе, IMC≥30kg/m^2 – obezitate. Obezitatea abdominală a fost diagnosticată la valori ale CA≥94 cm la bărbaţi şi ≥80 cm la femei şi/sau raport T/I ≥0,5.

S-au completat, faţă în faţă cu un intervievator antrenat, chestionare de frecvenţă alimentară, de evaluare a stresului perceput, de activitate fizică. După obiceiul de a fuma s-au structurat 3 grupe: nefumători, foşti fumători (abstinenţă >6 luni) şi fumători.

Pentru evaluarea nivelului de stres s-a folosit *Perceived Stress Scale* (Scala de Stres Perceput, *PSS*), cel mai utilizat instrument psihologic internaţional de măsurare a percepţiei stresului, tradus în limba română (8). Chestionarul cuprinde 10 întrebări (itemi) cu 5 variante de răspuns şi anume: 0 = Niciodată; 1 = Aproape niciodată; 2 = Uneori; 3 = Destul de des; 5 = Foarte des. Scorul la PSS se obţine prin răsturnarea punctajului (adică 0 = 4, 1 = 3, 2 = 2, 3 = 1 şi 4 = 0) la cei patru itemi consideraţi pozitivi (itemii 4, 5, 7 şi 8) şi apoi făcând suma tuturor itemilor. Interpretarea scorului se face în funcţie de sex: la bărbaţi - grad înalt de stres (GIS)=18-24 puncte, iar grad patologic de stres (GPS) >24; la femei – GIS=20,4-26,4 şi GPS >26,4.

Evaluarea activităţii fizice s-a făcut cu Chestionarul Internaţional de Activitate Fizică (*International Physical Activity Questionnaire, IPAQ*) (9) tradus în limba română, care are întrebări legate de intensitatea şi durata activităţii fizice la locul de muncă, în timpul transportului, în activitatea casnică şi pentru recreere şi sport. Nivelul de activitate fizică poate fi scăzut, mediu sau crescut.

Pentru evaluarea nutriţională s-a folosit un chestionar semicantitativ de frecvenţă alimentară adaptat (10) şi validat prin cercetarea anterioară în teritoriu (11). Se analizează alimentele “uzuale” care acoperă diferite aspecte ale vieţii pe parcursul ultimului an. Au fost incluse alimentele care contribuie la variaţia interindividuală a consumurilor, cum ar fi alimentele bogate în grăsimi sau în fibre. Chestionarul are 12 variante de răspuns pentru fiecare aliment sau grup alimentar chestionat (de la "aproape niciodată" la ">6 porţii/zi") şi întrebări despre modul de preparare a alimentelor. Anterior completării chestionarului se discută unităţile de măsură folosite, se estimează porţiile prin descriere şi raportare la elemente culinare cunoscute (lingură, linguriţă, cească, pahar etc). În chestionar se completează ca unitate o porţie standard. S-a chestionat consumul de cafea considerându-se ceaşca standard de 215 ml. S-au pus întrebări despre consumul de alcool. Fiecare tip de alcool este chestionat separat. Se consideră că un consum de < 2 porţii/zi la femei şi < 3 porţii/zi la bărbat este acceptat (1 porţie alcool=50ml tărie=150ml vin=350ml bere).

S-au folosit în analiza statistică SPSS (*Statistical Package for Social Sciences*) versiunea 19.0 pentru Windows în cazul analizei statistice aplicate, respectiv *Microsoft Office Excel* pentru crearea bazei de date (program compatibil cu SPSS în ceea ce priveşte importul datelor).Variabilele continui au fost exprimate ca medie ± DS, iar variabilele discrete ca număr şi proporţii. Determinarea intervalelor de variaţie a indicatorilor statistici şi testarea ipotezelor statistice s-a realizat cu interval de încredere de 95%, rezultând un prag de semnificaţie p = 5% = 0,05. Compararea grupurilor s-a făcut cu testul *t-Student* pentru variabilele continui şi cu testul Pearson Chi-Square (χ^2) pentru datele categoriale. Pentru χ^2 pragul de semnificaţie este p=1, adica p_{calc}<1.

REZULTATE

Structura lotului. În funcţie de IMC, 37,2% sunt normoponderali, o proporţie

mai mare a acestora fiind bărbaţi (50,8% bărbaţi); 44,2% sunt supraponderali, majoritatea femei (65,8% femei); 18,6% sunt obezi, marea majoritate a acestora fiind femei (71,9% femei). În ceea ce priveşte CA, 52,4% dintre normoponderali au CA groasă, marea majoritate a acestora fiind femei (78,8%). În ceea ce priveşte supraponderalii, numai 10,5% dintre aceştia au CA normală (dintre aceştia 75% fiind bărbaţi), restul de 89,5% fiind cu CA groasă (70,6% dintre aceştia fiind femei). În privinţa veniturilor medii/membru de familie/lună, participanţii au declarat: venituri <100 RON/lună în proporţie de 20,3%; 54,1% au declarat venituri între 100-400 RON/lună, 19,8% între 400-800 RON/lună, iar 5,8% au declarat venituri >800 RON/lună. Nivelul de studii al populaţiei : maximum 10 clase au 83,7 %, restul de 16,3% având mai mult de 10 clase cu extreme de la fără nici o clasă (3,5%) la studii universitare (1,2%).

Relaţia dintre statusul socio-economic şi indicii antropometrici:

Venit. S-a constatat diferenţă semnificativ statistică între venitul mediu lunar/membru familie şi IMC, în sensul că cei cu veniturile cele mai mici (<100 RON/lună) au IMC mai mic decât cei cu venituri mai mari (400-800 RON/lună), chi-square=0.024. In sublotul celor cu venit < 100 RON/lună, 60 % sunt normoponderali si doar 11,4% obezi, pe cînd în sublotul persoanelor cu venit > 400 RON/lună doar 23,5 % sunt normoponderali , 52,9% sunt supraponderali şi 23.5% sunt obezi

Ocupaţie. S-a constatat statistic semnificativ că pensionarii au IMC-ul cel mai mare, iar salariaţii IMC-ul cel mai mic (chi-square = 0,004). Totuşi, această constatare este greu de interpretat, odată ce creşterea ponderală este proporţională cu vârsta (11).

Studii. Există un trend către IMC mai mare în sublotul celor cu maximum 10 clase. Astfel, între normoponderali, 76,6% au max.10 clase, în sublotul supraponderalilor 86,8% au maximum 10 clase, iar în cel al obezilor 90,6% au maximum 10 clase.

Studiul factorilor de risc cardiovascular legaţi de stilul de viaţă:

Fumatul. În lotul studiat, 16,9% dintre subiecţi sunt fumători, 7% sunt foşti fumători, iar restul de 76,2% sunt nefumători. Am analizat doar grupele fumători şi nefumători, fără cel al foştilor fumători, care este prea mic. Putem afirma că IMC-ul la fumători este semnificativ mai mic decât IMC-ul la nefumători (p=0.049). Între normoponderali 26,6% sunt fumători, între supraponderali 11,8% sunt fumători, iar dintre obezi doar 9,4% sunt fumători. S-a obţinut semnificaţie statistică şi când s-a comparat CA a fumătorilor, cu a nefumătorilor (chi-square=0,003), fumătorii având CA mai mică decât nefumătorii. Între cei cu CA normală, 33,3% sunt fumători şi 56,4% sunt nefumători, iar între cei cu CA groasă: 12% sunt fumători, 82% fiind nefumători.

Consumul de alcool. În lotul studiat, 10,5% dintre subiecţi au declarat consum excesiv de alcool, restul de 89,5% neîncadrându-se în aceste criterii. IMC-ul celor care consumă excesiv alcool este statistic semnificativ mai mic decât cel al celor care nu consumă alcool excesiv (25,13kg/m^2 *vs.* 26,95kg/m^2, p=0,049). La fel, 19,5% dintre cei care nu consumă excesiv alcool au CA normală, faţă de 50% dintre cei care consumă excesiv alcool, care au CA normală. Astfel, statistic semnificativ (chi-square=0,003), cei care consumă excesiv alcool au CA mai mică.

Stresul. Persoanele cu un grad de stres înalt au în proportie de 80% CA peste valo-

rile admise, iar dintre persoanele cu grad patologic de stres 70,3% au talia groasă.

Relaţia între consumul de cafea zilnic şi indicii antropometrici. S-a constatat, statistic semnificativ, că cei care consumă zilnic de cafea sunt cel mai adesea supraponderali (chi-square=0,093). Astfel, între normoponderali, 56,2% consumă zilnic cafea, între supraponderali 72,4% consumă zilnic cafea, iar între obezi, 56,4% consumă zilnic cafea. Nu s-a constatat nicio relaţie statistic semnificativă între CA şi consumul de cafea, deşi există un trend spre creşterea CA la cei care consumă zilnic cafea. În schimb, dacă se face raportul T/I, se constată o diferenţă statistic semnificativă (chi-square=0,078), 65,6% dintre cei care au T/I≥0,5 consumă zilnic cafea.

Dieta. Am analizat următoarele aspecte ale dietei care cresc riscul cardiovascular: consumul a <5 porţii de fructe şi legume/zi şi consumul >10% din total calorii de grăsimi saturate. Doar 30,8% dintre subiecţi au declarat consumul zilnic de 5 porţii de legume şi fructe. Nu s-a constatat o corelaţie între consumul adecvat de fructe şi legume şi IMC. În ceea ce priveşte consumul de grăsimi saturate >10% din totalul caloriilor, 64,3% dintre subiecţi au declarat consum mai mare decât această proporţie (estimat prin înmulţirea frecvenţei consumului alimentelor care conţin grăsimi saturate cu cantitatea de grăsimi saturate/porţie, iar cantitatea a fost calculată pentru o dietă de 2500 kcal/zi pentru bărbaţi şi 2000 kcal/zi pentru femei). Nu s-a constatat o corelaţie între consumul de grăsimi saturate şi IMC, sau între consumul de grăsimi saturate şi CA, dar aplicând formula T/I, s-a constatat semnificaţie statistică, cei cu T/I<0,5 consumă mai puţine grăsimi saturate decât cei cu T/I ≥0,5 (media de 30,49 g/zi *vs*. 33,40 g/zi, test neparametric). Cele mai frecvent consumate alimente de către populaţia studiată au fost, în ordine: pâinea şi alte produse din cereale, fructe, ulei, lapte, legume şi ouă. S-a putut determina un pattern de tip vestic, predominent cu carne si mai ales cu alimente prăjite în contrast cu o alimentaţie sănătoasă cu lactate şi legume şi fructe, dar loturile comparate nu au dat semnificaţie statistică.

Sedentarismul. Aplicând *IPAQ*, în această populaţie rurală, analizată în anotimpul primăvară-vară, 11,6 % din populaţie este sedentară, 16,7% din populaţie este moderat activă, iar 71,7% din populaţie are activitate fizică mare. Aceste procente se referă la un sublot de 138 de subiecţi la care s-a aplicat chestionarul, care au vârsta ≤69 ani (peste această vârstă, chestionarul nu poate fi aplicat). Statistic semnificativ, IMC-ul persoanelor cu activitate fizică medie este mai mare decât al celor care fac activitate fizică mare (30,13 *vs*. 26,2, p=0,015). Activitatea efectuată de populaţia studiată este eminamente ocupaţională şi casnică.

DISCUŢII

Stilul de viaţă modern este asociat cu creşterea riscului cardiovascular printr-o prevalenţă ridicată a fumatului, sedentarismului şi obezităţii.

Evoluţia supraponderii şi obezităţii în comunitatea studiată este în trendul mondial (12). Deşi am găsit în lotul nostru că fumătorii au IMC şi CA mai mici decât nefumătorii, riscul cardiovascular al fumatului nu se exercită prin intermediul obezităţii şi lupta pentru combaterea lui trebuie continuată. Din literatură rezultă că persoanele cu obezitate viscerală fumătoare au cel mai mare grad de risc (13).

Dacă ne bazăm pe conţinutul energetic, un gram de alcool are 29 kJ (7,1 kcal), consumul de alcool ar induce creşterea în

greutate. Nu sunt însă studii relevante care să arate că odată cu creşterea consumului de alcool, creşte şi IMC (14). Se discută despre cantitatea şi mai ales tipul de alcool consumat (15). În studiul nostru, marii băutori au IMC şi CA mai mică probabil prin tulburări ale apetitului, printr-un grad de denutriţie, relaţia cu factorii de inflamaţie urmând a fi cautată ulterior.

Rezultatele noastre privind relaţia consum de cafea – indici antropometrici s-ar putea să fie în legătură cu consumul de cafea îndulcită cu zahăr, sau cu faptul că adesea consumul de cafea se asociază cu tulburări de somn, care sunt de fapt cele care conduc la suprapondere şi obezitate. Rolul benefic, de antioxidant al cafelei va fi căutat în relatie cu parametrii biochimici revelaţi şi de literatură (16).

Relaţia dietă – indici antropometrici nu a dat rezultante semnificative clinic la această etapă în relatie cu cuantumul caloric sau grupe de alimente. Numeroasele chestionare de frecvenţă alimentară găsite în literatura de specialitate şi-au dovedit valabilitatea raportate la "standarde de aur" cum ar fi o serie de biomarkeri, pe care noi îi vom studia în continuare (17). Nu am putut valida un *pattern* alimentar aterogen deşi multe persoane consumă o dietă cu carne şi prăjeli. Nici o dietă protectivă nu a putut fi clar delimitată, deşi printre principalele alimente consumate sunt lactatele, legumele, fructele şi uleiul. Întrebările legate de gastrotehnie arată însă o rară utilizare a uleiului crud.

CONCLUZII

Stilul de viaţă are influenţă asupra statusului ponderal al indivizilor evaluat prin indicii antropometrici. Obezitatea se corelează pozitiv cu vârsta, stresul şi nivelul redus de educaţie şi negativ cu gradul de efort fizic şi cu consumul excesiv de alcool. Dacă IMC evaluează global populaţia, când sunt de examinat influenţele unor parametri specifici ai stilului de viaţă, CA şi raportul T/I sunt mai sensibili. Continuarea cercetării ne va ajuta să definim şi alti parametri ai stilului de viaţă ca factori de risc independenţi ai riscului cardio-metabolic.

NEUROENDOCRINE FACTORS IN HYPERTENSION DURING PREGNANCY (Abstract): Pregnancy induced hypertension is a condition of high blood pressure during early and mid-pregnancy. This type of hypertension is much like the chronic type, but it occurs only when the woman is pregnant and resolves completely after delivery. **Aim:** to evaluate some stress hormones in both normotensive and hypertensive pregnant women. **Material and methods:** The study investigated the correlation between pregnancy induced hypertension and different immune/inflammatory and other markers. This exploratory investigation was performed on pregnant women diagnosed with pregnancy-induced hypertension, admitted to the Iasi Cuza Voda Hospital. The psychometric assessment was performed by using the daily stress test, daily hassle scale, blood pressure measurements, and determination of anthropometrical parameters. Some parameters, such as the neuroendocrine and immune/inflammatory ones, and specific parameters for pregnancy hypertension were determined. **Results and discussions:** Our study revealed that blood pressure values presented significant differences between systolic, but not diastolic blood pressure values ($p<0.05$). In 75% of subjects blood cortisol levels were not changed. Daily stress level assessment proved that low potential factors and an annoying environment had a high influence on both normotensive and hypertensive pregnant women. Hypertensive women also presented leukocytosis and thrombocytopenia. **Conclusions:** The research results proved that plasmatic cortisol level was higher in hypertensive pregnant women, comparing to the normotensive one. **Key words:** NEUROENDOCRINE, HYPERTENSION, PREGNANCY

Hipertensiunea arterială apărută în timpul sarcinii nu este în mod obişnuit periculoasă, ea fiind denumită "hipertensiune arterială tranzitorie a sarcinii". Totuşi, trebuie monitorizată atent, pentru că poate fi primul semn al unei stări patologice grave, preeclampsia.

Obiectivele cercetării au fost reprezentate de cercetarea nivelurilor unuia dintre hormonii de stres (cortizolul) la paciente care s-au adresat pentru consult in Ambulatoriul Spitalului Cuza Vodă din Iaşi, evaluarea gradului de stres prin teste psihometrice şi a unor parametri biologici, pentru identificarea de noi factori de prognostic în criza de hipertensiune arterială din sarcină.

MATERIAL ŞI METODĂ

Cercetarea în vederea stabilirii unor corelații neuro-imuno-endocrine în sarcină, ca

factori de prognostic în afecțiunile cardiovasculare din timpul sarcinii, a fost realizată printr-un studiu clinic pilot prospectiv unicentric, cu grupuri paralele, randomizat, la paciente diagnosticate cu criză acută de hipertensiune arterială. Comparația s-a realizat cu un lot martor, care a inclus gravide sănătoase din punct de vedere clinic şi al investigațiilor de laborator.

Studiul a fost aprobat de Comisia de Etică Instituțională.

Pentru început, a fost realizat un studiu pilot, care a inclus câte 6 paciente în fiecare lot, pentru a detecta eventualele modificări neuro-imuno-endocrine. Toate participantele incluse au semnat formularele de consimțământ pentru participarea la studiu, după ce au fost informate verbal şi în scris despre scopul şi modul de desfăşurare a studiului.

Criteriile de selecție a pacientelor au fost reprezentate de:

- ***Criterii de includere:*** vârsta: peste 18 ani; consimțământul scris înainte de introducerea în studiu; capacitatea de a înțelege natura şi scopul studiului; capacitatea de cooperare cu medicul şi de a îndeplini în cerințele studiului;
- ***Criterii de excludere:*** paciente cunoscute cu afecțiuni psihiatrice; cu traumatisme multiple; tratate cronic cu antiinflamatoare nesteroidiene sau cu corticosteroizi; refuzul subiecților; orice altă condiție care poate afecta participarea la studiu; persoane fără domiciliul stabil.

Evaluarea psihometrică s-a realizat cu ajutorul unui test de evaluare a stresului zilnic: Daily Hassles Scale. Cu ajutorul acestui test s-a putut evalua în ce măsură stresul a constituit o parte importantă a vieții în ultima lună. Testul evaluează frecvența şi modul de răspuns la factorii zilnici cu potențial de iritare (de exemplu, presiunea timpului, problemele financiare, evenimentele de la locul de muncă sau din familie, problemele din trafic etc). Testul are 51 de afirmații la care persoana care răspunde trebuie să acorde o valoare cuprinsă între 1 şi 4 (este aleasă valoarea 1, în cazul în care situația nu a reprezentat o parte importantă a vieții şi, gradat, se ajunge până la valoarea 4, ce corespunde situației ce a reprezentat o parte importantă a vieții).

Evaluarea clinică a constat în: măsurători ale tensiunii arteriale; determinarea parametrilor antropometrici (greutate, talie); pentru evaluarea indicelui de masă corporală au fost notate valorile dinainte de sarcină (pe baza acestor valori declarative s-a calculat indicele de masă corporală, IMC = G (kg)/T² (m²). Măsurarea greutății s-a realizat cu pacienta dezbrăcată, utilizând un cântar calibrat, standardizat şi etalonat conform normelor internaționale.

Datele anamnestice înregistrate au fost aspectele privind stilul de viață (consum de cafea, alcool, fumatul), afecțiunile cronice asociate, antecedentele heredo-colaterale de HTA asociată sarcinii, tratamentul urmat în mod curent.

Analiza statistică a datelor a fost realizată utilizând testul t-Student. Datele sunt prezentate sub formă de valori medii ± deviația standard. Diferențele au fost considerate semnificative pentru $p < 0,05$.

REZULTATE ŞI DISCUȚII

Caracteristicile demografice ale subiecților

Au fost incluse în studiu un număr de 24 de gravide, repartizate în două loturi: un lot de 12 gravide normotensive, cu vârsta medie de 27,5 ± 4,2 ani, cu limite între 22 şi 29 de ani (lotul martor); un lotul de 12 gravide hipertensive, cu vârsta medie de 26,75 ± 3,3 ani, cu limite între 26 şi 34 de

ani (lotul de studiu). S-a calculat indicele de masă corporală înainte de sarcină, care a fost cuprins între 20.39 şi 27.6, media fiind de 24.16 ± 6.32.

Date privind factorii de risc: stilul de viață al pacientelor cu hipertensiune arterială incluse în studiu

Studiul factorilor de risc cardiovascular la care sunt expuse pacientele incluse în studiu a relevat că aproximativ 80% din gravidele normotensive incluse în studiu declară consumul de cafea (o ceaşcă/zi, declarativ), în timp ce doar 20% dintre gravidele hipertensive asociază acest tip de comportament (fig. 1). Rezultatele studiului nostru sugerează că, deşi consumul de cafea reprezintă un factor de risc pentru dezvoltarea HTA, în cazul gravidelor, acesta nu se corelează permanent cu valori tensionale mari. Rezultatele obținute în cadrul studiului nostru se corelează cu cele din literatură (1,2).

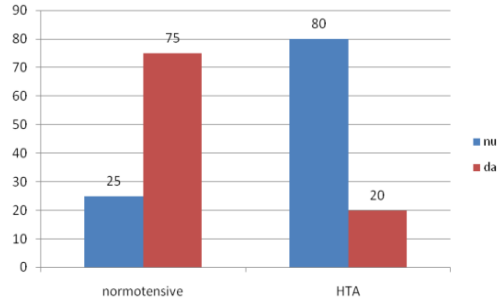

Fig. 1. Procentul consumatoarelor de cafea la loturile studiate

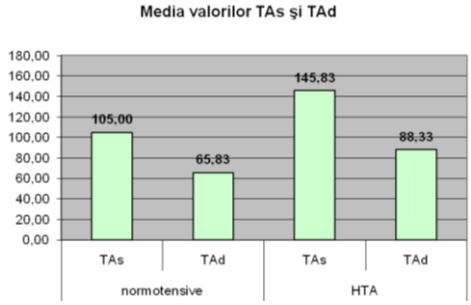

Fig. 2. Mediile valorilor TAs şi TAd la loturile studiate

Rezultate privind factorii de risc cardiovascular: valorile tensionale ale pacientelor incluse

În cadrul lotului martor, valorile TA sistolice (TAs) au fost cuprinse între 90-110 mmHg, iar cele ale TA diastolice (TAd), între 60-70 mmHg. În lotul gravidelor hipertensive, distribuția valorilor TAs s-a situat în intervalul 140-150 mmHg, în timp ce, TAd s-a menținut între 85-100 mmHg (fig. 2). Se observă că valorile TAs la lotul gravidelor hipertensive sunt nesemnificativ statistic mai mari, comparativ cu cele ale pacientelor din lotul normotensiv ($p>0,05$), în timp ce, diferența la nivelul valorilor TAd prezintă semnificație statistică ($p< 0,05$). Creşterea mai ales a valorilor TAd în context de sarcină explică semiologia afecțiunii şi organele afectate preferențial în cadrul crizei eclamptice (creier, ficat, rinichi). Rezultatele obținute se corelează cu datele din literatură care arată creşteri mai importante ale TAd, comparativ cu TAs, ceea ce sugerează că HTA asociată sarcinii determină, prin creşterea postsarcinii, manifestări clinice similare suprasolicitării cordului drept (3).

Rezultatele evaluării psihometrice (testul Daily Hassles)

Evaluarea nivelului stresului zilnic a demonstrat că factorii cu potențial scăzut de iritare au avut cea mai mare pondere, atât la gravidele normotensive, cât şi la cele cu HTA (fig. 3). Factorii stresori de intensitate mare şi extremă au apărut cu frecvență scăzută la ambele loturi, nici una dintre gravidele hipertensive nerelatând prezența unui stres extrem, în perioada evaluării. Pe de altă parte, s-a constatat că percepția tuturor categoriilor de factori

stresori a fost mai accentuată la grupul pacientelor cu HTA. Rezultatele studiului nostru sunt conforme cu datele din literatură, care arată o frecvență mai mare a HTA la persoane supuse stresului sau cu percepție puternică a agenților stresori (4).

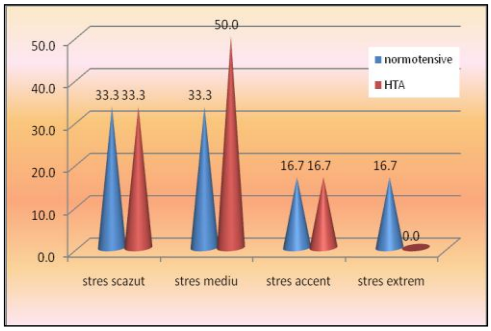

Fig. 3. Rezultatele evaluării psihometrice prin testul Daily Hassles, la pacientele incluse în studiu

Rezultate privind biomarkerii neuroendocrini

Studiul nivelului cortizolului total plasmatic a relevat că 25 % din pacientele incluse în studiu au avut valori normale ale cortizolului plasmatic total, în timp ce restul pacientelor au prezentat valori crescute ale acestui parametru. Valoarea medie a cortizolului plasmatic la pacientele hipertensive luate în studiu a fost de 248,72 ng/ml ± 125,66 (iar mediana a fost de 247,15 ng/ml). Cortizolul are valori normale cuprinse între 60-230 ng/ml între ora 8 şi 10 şi valori normale cuprinse între 30-150 ng/ml la ora 16. La gravide, în al treilea trimestru de sarcină, valorile cortizolului total plasmatic sunt mai mari decât valorile normale. Datele din literatură sugerează că există o influență reciprocă între glucocorticosteroizi şi steroizii sexuali în reglarea funcțiilor imune dependente de timus (5).

Efectele glucocorticosteroizilor pe celulele sistemului imun sunt mediate prin receptori membranari. Există două tipuri de receptori, notate cu I şi II. Tipul I leagă aldosteronul şi corticosteronul cu aceeaşi afinitate. Tipul II (situs de referință al dexametazonei) are afinitate scăzută față de corticosteron, comparativ cu tipul I. În creier şi hipofiza anterioară, una dintre multiplele acțiuni ale acestui receptor este implicată în reglarea feed-back-ului axei hipotalamo-hipofizo-corticosuprarenaliene în timpul răspunsului la stres. Glucocorticosteroizii secretați în timpul stresului acționează pe hipocampus, hipotalamus, hipofiză, pentru a inhiba secreția corticotropinei şi a ACTH şi pentru a termina răspunsul la stres.

Răspunsul imun celular şi umoral este mai activ la femei decât la bărbați, cu excepția perioadei de sarcină. Existența unui dimorfism sexual în răspunsul imun, alterarea marcată a funcției imune induse de gonadectomie, şi alterările imunitare din sarcină, susțin teoretic ipoteza că steroizii gonadali intervin în reglarea funcțiilor sistemului imun. Beneficiul dimorfismului imunologic poate fi parțial legat de capacitatea femeilor de a rezista la stresul reproducerii. Hormonii sexuali sunt principalii factori ai dezvoltării, reglării şi menținerii dimorfismului, deşi intervin şi alți hormoni, cum ar fi, hormonul de creştere, prolactina, glucocorticosteroizii, precum şi o serie de mediatori clasici (5).

Niveluri crescute de corticosteroni, precum şi variații mari ale corticosteronului plasmatic au fost găsite la femei în timpul zilei şi ca răspuns la stres. Datele obținute în acest studiu demonstrează depăşirea posibilităților de intervenție a axei hipotalamo-hipofizo-corticosuprarenaliene în menținerea homeostaziei organismului la gravidele hipertensive (6).

Rezultate privind biomarkerii imuni/ inflamatori

Studiul valorilor formulei leucocitare a demonstrat existența de modificări semnificative, comparativ cu valorile normale la gravidele hipertensive (10200 ± 233 globule albe/ml comparativ cu 8200 ± 361 globule albe/ml în lotul cu gravide normotensive) (fig. 4). Leucocitoza este considerată în limite normale pentru trimestrul al II-lea sau al III-lea de sarcină.

Leucocitoza obținută la gravidele hipertensive evidențiază una din caracteristicile sindromului HELLP (denumire provenită din abrevierea în limba engleză a principalelor modificări de laborator: anemie hemolitică, creşterea nivelului enzimelor hepatice şi trombocitopenie), cu sau fără eclampsie, datele fiind confirmate în literatura de specialitate (6,7).

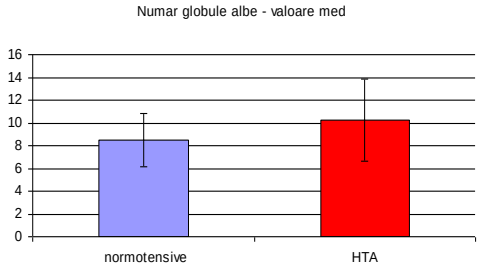

Fig. 4. Valorile medii ale numărului de globule albe

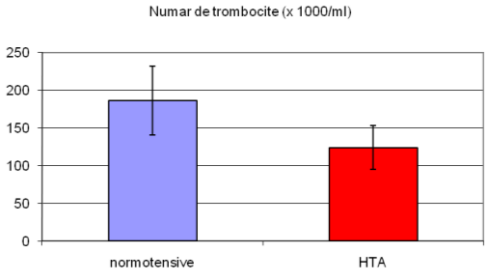

Fig. 5. Valorile medii ale numărului de trombocite.

Rezultate privind alți biomarkeri

Studiul valorilor seriei eritrocitare (număr de eritrocite, hemoglobină şi hematocrit) nu a demonstrat existența de modificări patologice ale acestor parametri. Valorile medii ale trombocitelor la gravidele normotensive au fost 186000 ± 45600 /ml trombocite, comparativ cu 124000 ± 28900 trombocite/ml la gravidele hipertensive. Studiul valorilor trombocitelor a demonstrat existența de trombocitopenie la două dintre gravidele cu hipertensiune arterială incluse în studiu (fig. 5). Datele sunt confirmate de literatura de specialitate, trombocitopenia fiind descrisă la 70 % dintre gravidele cu sindrom HELLP cu eclampsie şi 30 % dintre gravidele cu sindrom HELLP fără eclampsie (7).

Valorile medii ale lactic dehidrogenazei (LDH) la gravidele normotensive au fost 207 ± 54,2 U/L, comparativ cu 263 ± 61,8 U/L la gravidele hipertensive. Studiul valorilor acestui parametru a demonstrat existența de valori uşor peste limita normalului la gravidele cu hipertensiune arterială incluse în studiu (fig. 6).

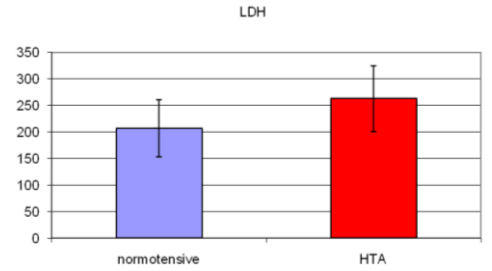

Fig. 6. Valorile medii ale LDH

Studiul altor parametri nu a demonstrat existența de modificări patologice la persoanele incluse în studiu. Astfel, deşi în literatura de specialitate există studii care evidențiază creşteri ale valorilor transami-

nazelor serice (6,7), nici una dintre gravidele hipertensive luate în studiu nu au prezentat modificări semnificative ale acestor parametri.

CONCLUZII

Cauzele şi mecanismele de producere ale HTA de sarcină nu sunt pe deplin elucidate, iar etiologia rămâne necunoscută. Există şi cazuri în care unele femei dezvoltă hipertensiune în timpul sarcinii, preeclampsie, chiar în lipsa acestor condiţii medicale preexistente.

Dintre markerii pentru factorii de risc se pot menţiona:

- sangvini: hematocrit, trombocite, produşii de degradare ai fibrinei, factorii VIII de coagulare, antitrombina III, timpul de protrombină, aspartat aminotransferaza (ASAT), alanin aminotransferaza (ALAT), bilirubina, acidul uric, creatinina, ureea, fibrinogenul, clearance-ul creatininei, trigliceridele, acizii graşi liberi, anticorpii antinucleari, anticorpii antifosfolipidici (8);
- urinari: volumul, densitatea, sedimentul, proteinuria, ionograma, calciuria.

Rezultatele cercetării au evidenţiat că valorile cortizolului plasmatic au fost crescute la gravidele diagnosticate cu valori crescute ale tensiunii arteriale, comparativ cu valorile acestui parametru la gravidele cu valori normale ale tensiunii arteriale, fiind corelate cu factorii de risc aparţinând stilului de viaţă şi cu biomarkerii inflamatori (leucocitoza), precum şi cu o serie de parametri (trombocitopenia) ce caracterizează sindromul HELLP cu şi fără eclampsie.

Persoanele incluse în studiu nu au prezentat modificări semnificative ale altor parametri ce caracterizează sindromul HELLP (de exemplu, hemoliza sau creşteri ale valorilor transaminazelor serice).

DEPRESSION SCREENING IN PATIENTS WTH CHRONIC OBSTRUCTIVE PULMONARY DISEASE (Abstract): The **aim** of this study was screening for depression in patients with COPD. **Material and methods:** Depression was diagnosed with the Hamilton 17 items questionnaire. All patients were assessed by history taking, physical exam, blood pressure (BP), spirometry, heart rate (HR), mMRC scale (Modified research Council). **Results:** The study included 312 patients with COPD admitted in the Clinical Hospital of Pneumology Iasi during 1-st March 2015 to 1st March 2017. The subjects were mainly males, with a median age of 65.4±4.1 years, a history of current or former cigarette smoking of 30 packs-year. Items of Hamilton Questionnaire: Item 5 (72%) - Mark 1-2-3 times night awaking, without problems feeling asleep again. Item 7 (50%) - Marks 2,3,4, Decreased performance, considerable loss of interest, frequent abandon of fulfilling tasks, even for those essential, lack of decisions, hesitations (directly or indirectly described). mMRC Dyspnea Grades/patient: Grade 3. **Conclusions:** 70% of COPD patients have low to moderate depression. 100% of subjects are former or current smokers, which is a known risk factor for COPD. 89% of patients were diagnosed with moderate to severe airway obstructive dysfunction. **Keywords:** DEPRESSION, COPD, HAMILTON QUESTIONNAIRE, mMRC SCALE.

Diagnosing depression in patients with chronic obstructive pulmonary disease (COPD) with severe or medium ventilatory deficiency is important for the management of the life quality of these patients.

According to the *Global Diagnostic, Treatment and Prevention Strategy* (GOLD Programme, 2017) COPD is a disease characterized by reduce air inflow, not completely reversible. The limitation of the air influx is usually progressive and associated with an abnormal pulmonary inflammatory response towards noxious particles or gasses (cigarettes smoke or other inhalatory irritants (1).

World Health Organization (WHO) estimates that 210 million people suffer from COPD globally and 3 million died in 2005. COPD is associated with a high morbidity and mortality and a considerable decreased quality of life in the late stage of the disease, representing an important socio-economic problem, through its high direct and indirect medical costs1. Recent research showed that COPD was the third mortality cause worldwide in 2010. This data represents a betted situation in comparison with previous predictions and show that the global mortality through COPD decreased in 2010 reported to 1990, from

6.4% to 2% (2).

However, in Romania COPD frequency increased: in 1990 it was 0,49%; in 20 years, it tripled, to 1.51% in 2010. The number of cases grew with 185% in this period. In 2010 over 1 million persons were diagnosed with COPD.

The clinical picture of COPD includes specific and unspecific respiratory symptoms, such as exertional and rest dyspnea, chronic cough, expectoration, wheezing and chest compression sensation. The cough is chronic, frequently productive, with mucous or purulent sputum, during infectious exacerbation, the so-called morning "bronchial cleansing". By far the most discomfort for the COPD patient is the dyspnea - the central symptom in those seeking medical attention. Its appearance is progressive, first in high exertional effort (running), the patient can no longer sustain the same effort as his age matched healthy subjects (3). Epidemiologic studies that along with the evolution of the respiratory disfunction the dyspnea aggravates and represent a major cause for the deterioration in the life's quality.

The spirometry is a valuable diagnostic and monitoring tool in COPD. It increases the diagnostic accuracy of chronic respiratory diseases and facilitates the treatment's improvement. A good spirometry assessment implies trained staff, good equipment and well standardized measurement procedures (4).

COPD diagnosis includes clinical history, physical examination, thoracic X-Ray and spirometry airways obstruction documentation (5, 6).

Treatment for obstructive dyspnea includes inhaled bronchodilators (anticholinergics, β2-agonists) and corticosteroids, recently added in a single inhaler, improve treatment adherence (4). Inhaled Thiotropium can increase bronchodilation but has little effect on the quality of life in COPD5. Recent research on IL-13 blockade with various monoclonal antibodies suggests that these could also be useful in the treatment of respiratory obstruction (6).

Depression is defined in 2012 by WHO as a common mental condition, including a depressive status, loss of interest and pleasure, decreased energy, guilt feeling or low self-esteem, sleep or eating disorders and reduce concentration (Depression: A Global Crisis - World Health Organization, 2012). Depression is a general emotional state, that involves the whole person (physically and psychic) and manifests through social retire, sorrow, with a global painful impression of hopelessness, fatality despair, longer than a justified reason (Kerneman dictionary, 2010). Depression is defined as a mental illness characterized by a profound change of the timic disposition towards sadness, moral suffering and lower psychomotor activity, associated with anxiety. It can associate delirious ruminations of culpability, indignation, self-appreciation and can progress to suicidal ideation or action. Depression symptoms can be complex and vary considerable from one person to another. As a rule, the person is depressed, sad, hopeless and loose interest in joyful things (7). The symptoms persist for weeks or months and interfere with work, social and family life.

The psychological symptoms include: continuous low mood or sadness, hopelessness, irritability and intolerance towards others, loss of motivation and interest, low decision-making, no happy feeling, anxiety or worry, suicidal or self-harm ideation (8).

Physical signs include: bradylalia and lent movement; appetite changes; low en-

ergy and libido, unexplained pain, constipation, sleep change (difficult sleeping at night and very early awakening)8.

Social symptoms include: fewer social activities and less contact with friends; neglect of hobbies and interests, difficulties in family life and home activities (8).

These component elements of depression are depicted in figure 1.

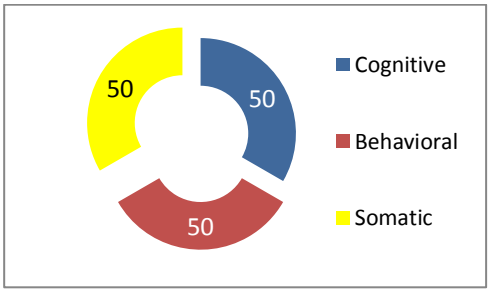

Fig. 1. Depression's components

Depression diagnosis is based on history taking and physical exam. First step is the medical appointment. The examining physician can evaluate the state of mental health of the patient through an interview or indicate a battery of verbal and written tests which diagnose depression. Some clinicians use diagnostic scales, represented in questionnaires by scores that pinpoint the amplitude of patient's sufferance.

A routine specific questionnaire is recommended to assess in due time subjective and affective symptoms and apply a therapeutic intervention to prevent their evolution. WHO and *The American Psychiatric Association* suggest considering symptoms which are present for at least 2 weeks to ease the questionnaire's delivery. The obtained results are diagnostic, especially in elderly (*Depression and anxiety scale; Hamilton's questionnaire 17 items; Beck questionnaire*).

AIM OF THE STUDY

The present study investigated the presence of depression in patients with COPD.

MATERIAL AND METHODS

Inclusion criteria were the following: Caucasian patients, age over 40 years old; with smoking history.

Exclusion criteria: lack of compliance, alcohol intake and drugs in the last 12 months, other major mental health disease, epilepsy, cardiac implanted pacemakers, decompensated heart disease (heart failure, untreated hypertension, angina pectoris, rhythm or conduction disturbances), rheumatic or neuromuscular active disease, low testosterone levels disease such as Klinefelter syndrome, chemo- and radiotherapy for cancer, excessive alcohol intake, Kallman syndrome, pineal gland or hypothalamic tumor, severe acute pathologies that needed hospital admission in the last 12 weeks, other respiratory diseases (idiopathic pulmonary fibrosis, bronchiectasis, pulmonary tuberculosis, bronchial asthma, diagnosed malignant tumors with radio or chemotherapy).

Depression was diagnosed with the Hamilton 17 items questionnaire.

All patients were assessed by history taking, physical exam, blood pressure (BP), spirometry, heart rate (HR), peripheral oxygen saturation in ambient air, mMRM scale (Modified research Council).

RESULTS

The study included 312 patients with COPD admitted in the Clinical Hospital of Pneumology Iasi between the 1st of March 2015 and 1st of March 2017. The subjects were mainly males, with a median age of 65.4±4.1 years, a history of current or former cigarette smoking of 30 packs per year.

TABLE I

Items of Hamilton Questionnaire

Item 1	61.1%	Mark 1	The symptoms are due to hidden sadness in every person. It can be discovered only if the subject is asked and is manifested as a feeling of lack of wellness, indisposed, discouraged, pessimist, sad; higher than an occasional feeling. Can be eased by company, work, activity.
Item 2	55%	Mark 1	Poor self-esteem, with a persistent regret for past actions, self-reproaches, feeling of having caused a prejudice to other people
Item 3	61.1%	Mark 1	Lack of symptoms. In some subjects there is a feeling that life can't be lived (7%)
Item 4	67.1 %	Mark 1	Discrete difficulty in falling asleep (duration of 30-60 minutes). The duration up to 30 minutes is considered normal
Item 5	72%	Mark 1	time night awaking, without problems feeling asleep again
Item 6	68%	Mark 1	The subjects awake one hour prior to the usual awaking time, but goes back to sleep without difficulties
Item 7	50%	Marks 2,3,4,	Decreased performance, considerable loss of interest, frequent abandon of fulfilling tasks, even for those essential, lack of decisions, hesitations (directly or indirectly described)
Item 8	40%	Mark 1	Discrete decrease in conversation, communication, fixed expression, or fluctuation of the emotional response
Item 9	63%	Mark 1	Fidgeting of hands, hair, or feet (restless persons)
Item 10	68%	Mark 1	Subjective tension and irritability – not fundamented worries, intermittent tensions
Item 11	72%	Mark 1	Increased intensity and severity of symptoms, that appear more frequent than twice a week
Item 12	64%	Mark 0	Normal appetite
Item 13	80%	Mark 1	Tiredness disproportionate to the made effort, back pain, headache or member pain, low energy, fatigability
Item 14	60%	Mark 1	A small decrease in interest or a decrease in activity
Item 15	70%	Mark 1	Fixed attention on own body, evidenced when asked, but not apparent spontaneously in the conversation
Item 16	80%	Mark 1	Loss of weight related to the actual disease
Item 17	70%	Mark 1	Mark 1– Partial loss. The patients acknowledge his/her disease, but attributes it to food, climate, workload, and silence need

DISCUSSION

The aim of this study was screening for depression in patients with COPD. Most of enrolled patients were over 65 years old, current or former smokers, with 30 pack cigarettes / year history.

This study is similar with Thomas George Willgoss work, who searched pneumology journals from 1966 to 31st of January 2012 for articles focused on clinical interviews to assess a psychologic diagnostic in patients with COPD. The study found a frequency of 55% for current depression in COPD patients, consistent with our study. This is a moderate to increased value, but with over symptomatology – clinic, psychologic and psychiatric (9).

One of the most severe symptoms is the decreased work capacity, over the accepted minimum, with decreased work performance and lack of efficiency, impossible to hide, inducing commentaries, making chores impossible, complete disorganized work, lack of hygiene and self-neglect, friends' abandon.

These patients become unable to handle themselves in life, society and seek the hospital for protection (not for investigations or observation). They abandon work due to their disease and need consistent help of friends and neighbors for living.

The limitations of this study consist in its low number of patients, the rate of COPD patients understanding of the task of 80%, 20% of subjects not responding due to a cluster of mental problems, which make impossible for them to understand the questions or the possible answers in the questionnaire.

CONCLUSIONS

70% of COPD patients have low to moderate depression.

All the subjects are former or current smokers, which is a known risk factor for

COPD.

89% of patients were diagnosed with moderate to severe airway obstructive dysfunction.

COPD is of the most severe public health problems, and the fourth global mortality cause. Being a chronic, progressive and not curable disease, the medical treatment can reduce symptoms and reduce the airway obstructive dysfunction.

Recent studies started to recognize the importance of the psychological factors in COPD progression and the need to consider their management. High prevalence of depression in COPD is consistent with a poor evolution.

More inclusive evaluation of anxiety and depression through specific tests (psychologic, psychiatric, antismoking and antialcohol counselling) associated with pulmonary rehabilitation in COPD can result in life's quality improvement.

NON-INVASIVE MARKERS TO ESOPHAGEAL VARICES IN COMPENSATED LIVER CIRRHOSIS (Abstract): **Material and methods**: There were 91 patients in this study, with liver cirrhosis classified as Child A, diagnosed using clinical, biological and ultrasound methods, and a control group. We used a special questionnaire and biostatistical methods in order to assess the presence of esophageal varices (EV), followed by performing upper gastrointestinal endoscopy (UGE). **Results**: Models made with biostatistical methods differentiated the cases with or without EV. ROC curve showed sensitivity and specificity values of various parameters. We obtained an overall rate of correct classification of 84.62% for the presence of EV and 71.30% scale assessment. **Conclusions**: Using non-invasive tests may be useful as therapeutic and prognostic considerations, to reduce the number of upper gastrointestinal endoscopy in the disease surveillance also. **Key words**: EPIDEMIOLOGY, LIVER CIRRHOSIS, ESOPHAGEAL VARICES

În România, patologia hepatică cunoaşte o incidenţăcrescută ca urmare a evoluţiei endemice a infecţiilor cu virusul hepatitei B (VHB) şi C (VHC) şi a consumului de alcool (1). Studiile efectuate au evidenţiat valoarea de prognoză asupra prezenţei cirozei hepatice şi a varicelor esofagiene (VE), a unui număr mare de parametri individuali accesibili, alături de metodele reprezentate de puncţia biopsie hepatică şi elastografia Fibroscan sau Fibromax (2).

Numeroase încercări au reuşit să îmbunătăţească valoarea predictivă şi a testelor sangvine simple sau în combinaţii, între care sunt scorurile APRI, ASPRI, AAR, ARI, Pohl, Forne, care folosesc date biochimice şi hematologice (3,4,5). Cu scopul de a valida rezultatele obţinute anterior, au fost analizate acurateţea, reproductibilitatea şi funcţia de prognoză a datelor estimate în modelul precedent, într-un lot nou de pacienţi recrutaţi după criterii similare.

MATERIAL ŞI METODĂ

Studiul de tip prospectiv s-a desfăşurat în perioada 1.01.2009-1.11.2010, în compartimentul de gastroenterologie al Spitalului Judeţean "Mavromati", Botoşani, pe un lot de 91 pacienţi diagnosticaţi cu ciroză hepatică, clasa Child A, prin metode clinice, biologice şi ultrasonografice. S-a utilizat o fişă de evaluare complexă, alături de calculul matematic propus pentru estimarea prezenţei VE, urmat de efectuarea endoscopiei digestive superioare. S-a folosit clasificarea VE în absenţa şi prezenţa, respectiv gradul 1 (VE care dispar la insuflarea endoscopică), gradul 2 (VE care nu confluează, dar protruzează în

TABELUL I
Calcularea indicatorilor SPRI, ASPRI, AAR, APRI, API

Indicator	Calcul
SPRI	Diametrul longitudinal al splinei (cm) / nr. trombocite (10^6 / ml) * 100
ASPRI	Vârsta (ani) : <30 = 0 ; 30-39=1 ; 40-49=2 ; 50-59=3 ; 60-69=4 ; =70=5
	ASPRI = vârsta + SPRI
AAR	TGP/TGO
APRI	TGP/42/ nr. trombocite*100
API	API=vârsta + nr. trombocite
	Vârsta (ani) : <30 = 0 ; 30-39=1 ; 40-49=2 ; 50-59=3 ; 60-69=4 ; =70=5
	Nr. trombocitex1000, >225=0,200-224=1,175-199=2,150-174=3,125-149=4, <125=5

lumen, sub insuflaţie endoscopică) şi gradul 3 (VE care confluează şi proemină în lumen). Pentru prelucrarea statistică, s-a mai utilizat clasificarea în VE mici, corespunzător gradului 1 şi VE mari, care cuprind gradele 2 şi 3 (6, 7).

Criteriile de excludere s-au referit la pacienţii cu carcinom hepatocelular primar, cu sângerare variceală în antecedente, cu tromboză portală la examinarea ecografică şi alte cauze pentru splenomegalie, precum şi cei aflaţi în tratament cu antagonişti ai receptorilor beta-adrenergici.

Parametrii urmăriţi au fost serologici (nivelul trombocitelor, valoarea TGP, TGO) şi ecografici (valoarea diametrului maxim al splinei, în combinaţii sub forma scorurilor SPRI, ASPRI, AAR, APRI, API) (tab. I).

Analiza statistică s-a realizat utilizând programele Microsoft Excel şi SPSS 16.0., testul t-Student şi chi^2, analiza univariată şi multivariată prin regresie logistică. Curba ROC (Receiver Operating Characteristic Curve) a folosit la calculul celei mai reprezentative valori, prin sensibilitate si specificitate, putând considera, astfel, valorile de cutoff ale diverşilor parametri. De asemenea, acurateţea modelului s-a apreciat prin măsurarea ariei de sub curba ROC, astfel, o arie $< 0,7$ a fost considerată bună, iar o valoare $> 0,8$ a indicat o acurateţe excelentă. Datele au fost exprimate ca medie a valorilor, cu un interval de încredere de 95%. S-a utilizat şi analiza dispersională univariată, obţinând indicatorii statistici ai variabilei dependente, total şi pe grupuri (testul Levene), pentru analiza omogenităţii dispersiilor (testul ANOVA), iar, în cazurile când dispersiile au fost diferite, s-a calculat semnificaţia diferenţei dintre medii prin testele robuste Welch sau Brown-Forsythe. Aprecierea semnificaţiei globale a modelului s-a realizat prin aplicarea testului Hosmer-Lemeshow (8,9). S-a propus un model logistic de prognoză în urma calculului matematic al lotului 1, cu verificarea datelor estimate in lotul 2.

REZULTATE

Lotul 2 (experimental) a cuprins 91 pacienţi, 47 femei şi 44 bărbaţi, în vârstă de 19-80 ani, cu o medie de 51, faţă de lotul 1 (martor), cu vârsta de 19-85 şi o medie de 52 ani. Intervalul de vârstă 40-59 ani a fost dominant. Analizând caracteristicile etiologice ale lotului 1 si 2, s-a observat o distribuţie relativ omogenă a principalelor etiologii reprezentate de consumul de alcool singur (28% lot 1, 30% lot 2) sau în asociere (18% lot 1, 15% lot 2) şi implicarea VHC (29%) (fig. 1).

Rezultatele obţinute după examinarea prin endoscopie digestivă superioară s-au exprimat, comparativ, prin clasificarea în grade (absente, 1, 2, 3). Am constatat diferenţe mici în repartiţia pe grade a VE, totuşi, semnificative, mai ales la categoria absente, 29% în lotul 1 faţă de 36% în lotul 2 şi pe palierul VE de gradul 2, unde datele arată o incidenţă de 24% în lotul 1 şi 18% în lotul 2 (fig. 2).

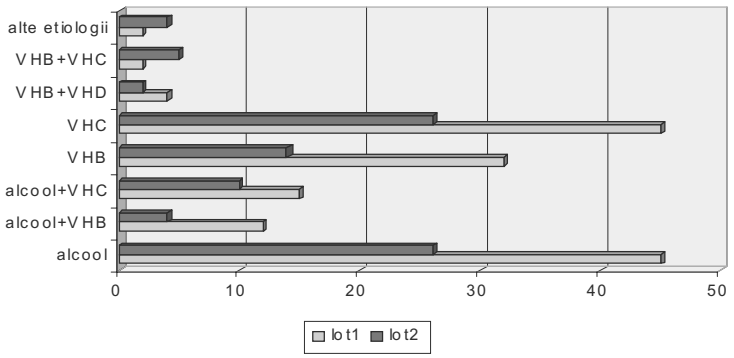

Fig. 1. Reprezentarea spectrului etiologic, comparativ în lotul 1 şi 2

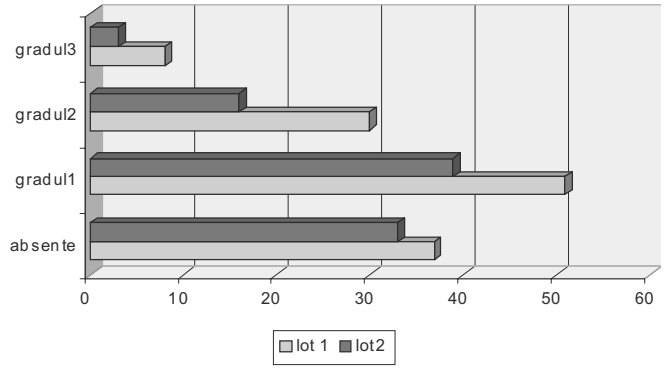

Fig. 2. Repartiţia varicelor esofagiene pe grade, comparativ în lotul 1 şi 2

A fost calculată valoarea modelelor propuse în cadrul lotului experimental şi anume, corelaţia scorurilor ASPRI, SPRI, AAR, API, APRI cu prezenţa sau absenţa VE, respectiv cu gradul acestora, determinat endoscopic. S-a constatat că singurii parametri cu semnificaţie statistică sunt SPRI şi ASPRI, valoroşi pentru ambele evaluări de detecţie a prezenţei VE, cât şi de corelare cu mărimea VE. Pentru restul indicatorilor, AAR, API, APRI, care sunt alcătuiţi din combinaţii de parametri biochimici, nu s-a demonstrat o asociere semnificativă (tab. II, III).

Utilizând datele care caracterizează lotul 2, s-a estimat un model logistic pentru prezenţa/absenţa VE. Rezultatele obţinute în urma estimării modelului arată că acesta este semnificativ statistic cu o semnificaţie globală a modelului indicată de testul Hosmer-Lemeshow de 0,172 (chi-square 11,55 şi grade de libertate 8). De asemenea, analiza valorilor rezumative denotă o bună concordanţă a modelului cu datele introduse astfel circa 56,9% (Nagelkerke R Square) din varianta iniţială este regăsită în model.

În privinţa valorilor prognozate de model, s-a obţinut un procentaj global al clasificărilor corecte de 84,6%, indicând o bună adecvanţă a modelului. Se poate observa că are loc o clasificare mai bună pentru cazurile de absenţă a VE (87,8%) decât pentru cele de prezenţă (82,7%).

Un alt model logistic matematic s-a obţinut după analiza coeficienţilor modelului 1, care va fi verificat pentru prognoza în lotul 2. Această funcţie a fost calculată pentru valorile SPRI şi ASPRI ale pacienţilor din lotul 2, utilizând curba ROC pentru a găsi valoarea de cut-off, care permite o prognoză acceptabilă. Utilizând funcţia logistică cu pragul de clasificare de 0,5, pentru lotul 2,

API	0,43	0,513	0,54	0,592	0,17	0,32	-0,46	0,81
APRI	0,81	0,371	0,90	0,372	0,29	0,32	-0,35	0,92

TABELUL III
Compararea grupurilor determinate de VE mari / mici

Testul	Egalitatea dispersiilor - testul Levene		Egalitatea mediilor - testul t		Diferența mediilor			
scor	F	p	t	p	Diferența	Er. std.	IC 95% al diferenței	
							Inf.	Sup.
SPRI	9,32	0,003	3,91	0,001	7,95	2,03	3,72	12,18
ASPRI	8,69	0,004	3,94	0,001	7,75	1,97	3,66	11,84
AAR	1,59	0,211	-1,32	0,190	-0,10	0,08	-0,26	0,05
API	0,86	0,356	0,28	0,777	0,11	0,38	-0,65	0,86
APRI	1,99	0,162	1,01	0,314	0,38	0,38	-0,37	1,13

s-a obţinut un procentaj de 68,03% de clasări corecte, cu precizarea că modelul prognostichează mai bine cazurile de prezenţă a VE (73,68%) decât cazurile de absenţă a VE (48,15%).

Analiza ROC pe cele două loturi, experimental şi martor, ne-a permis o apreciere a acurateţei modelelor şi a asigurat stabilirea unor valori cutoff. Deoarece semnificaţia statistică a fost $< 0,001$, a rezultat că modelul face o distincţie semnificativă între cazurile cu VE prezente, respectiv absente. Din analiza datelor, rezultă că VE prezente au fost prognosticate corect (82,7%) şi 12,1%, cazuri fals pozitive. Analiza similară în cadrul unui nou model privind clasificarea VE în mici şi mari a evidenţiat rezultate semnificative (tab. IV).

Utilizând funcţia logistică cu pragul de clasificare de 0,5 s-au obţinut date care atestă că în 71,3% cazuri, clasările au fost corecte, cu precizarea că modelul prognos-

a. **b.**

Fig. 3. Curba ROC pentru modelul prezentei VE mari/mici: **a.** în lotul 2; **b.** prognozate de analiza lotului 1

tichează mai bine cazurile de VE mici (85,5%) decât cazurile de VE mari (47,8%) (tab. V).

Pentru a realiza o clasare mai bună, s-a utilizat analiza ROC în care, pentru lotul experimental, discriminarea VE mari/mici obţine o valoare de 0,819, iar pentru lotul martor, de 0,741 (fig. 3 a, b).

Semnificaţia statistică fiind $<0,001$, rezultă că modelul face o distincţie foarte bună între cazurile VE mari şi VE mici. Astfel, de exemplu, alegând cutoff =-1,13748, va rezulta un prognostic corect, pentru cazurile cu VE mari (63,2%) şi cazuri fără VE, prognosticate fals pozitiv (12,5 %).

DISCUŢII ŞI CONCLUZII

Utilizarea testelor non-invazive propuse pentru diagnosticarea prezenţei şi dimensiunilor VE în cadrul evoluţiei cirozei hepatice poate fi utilă, atât din considerente terapeutice şi prognostice, cât şi pentru reducerea numărului de endoscopii digestive superioare şi pot fi repetate în cadrul monitorizării evoluţiei bolii.

Patogenia infecţiilor cu VHB şi VHC şi alcoolismul au fiecare particularităţi care se reflectă, în final, în producerea fibrozei hepatice. Mărimea splinei s-a dovedit a fi un parametru important în boala hepatică cronică, fiind corelată cu transformările fibrotice hepatice şi poate susţine singură diagnosticul de ciroză hepatică forma compensată în 82-88% din cazuri. În studiul nostru anterior (10), splenomegalia s-a dovedit alături de trombocitopenie parametru independent semnificativ corelat cu prezenţa VE, dar cu o acurateţe mai mică la măsurarea ariei ROC decât raportul lor calculat sub forma scorurilor SPRI şi ASPRI. Trombocitopenia are o corelaţie inversă cu mărimea VE şi corelaţie directă cu progresia fibrozei hepatice.

Analiza univariată şi multivariată a confirmat puterea de predicţie a combinaţiilor ce folosesc dimensiunile splinei, nivelul trombocitelor, vârsta şi acurateţea redusă a scorurilor ce folosesc nivelul transaminazelor TGP, TGO. Astfel, este de menţionat că doar ASPRI şi SPRI şi-au menţinut constantă acurateţea în toate analizele, aceste două scoruri fiind cele mai promiţătoare. Nu s-a putut stabili o valoare universală de cutoff, reproductibilă pentru ASPRI şi SPRI prin analiza matematică pe cele două loturi. În schimb analiza pe subloturi grupate pe etiologiile dominante arată ca o valoare prag >12 pentru ASPRI în hepatopatiile cu VHB şi >16 cu VHC are o valoare predictivă pozitivă pentru prezenţa VE (92%).

Analizând modelul experimental am obţinut un procentaj global de 84,62% pentru clasificarea corectă a cazurilor cu prezenţa VE. Exprimată în valori practice 10 pacienţi care aveau prezente la examenul endoscopic VE au fost diagnosticaţi fals negativ în model. Valoarea diagnostică a scăzut considerabil când s-a aplicat funcţia de prognoză la lotul martor când cu un procentaj global de clasificări corecte de 68,03%, 25 cazuri au fost greşit diagnosticate. În ceea ce priveşte modelarea după mărimea VE am obţinut două loturi care au dovedit semnificative la analiza prin testul Hosmer. Se menţine însă procentajul optim pentru prognoza mărimii VE (mari/mici), cu un total al clasificărilor corecte de 85,7% cu 11 cazuri prognozate ca având VE mari fals negative, unde practic s-ar fi pierdut momentul introducerii prevenţiei. Datele obţinute după aplicarea funcţiei de prognoza din analiza realizată lotului 1 şi aplicată lotului 2, în privinţa diagnosticării mărimii VE a determinat un procentaj global de 71,3% de clasificări corecte, cu o prognoză mai bună pentru cazurile cu VE mici de 85,5%, dar 24 cazuri au fost subevaluate în privinţa nivelului VE mari.

WHAT CAN HIDE BEHIND A DEEP VENOUS THROMBOSIS? CASE REPORT (Abstract): Deep venous thrombosis is frequently associated with various malignancies and, in particular, with pulmonary ones and is two times more common in patients with malignancies than those without. Recognition or diagnosis of a DVT as a paraneoplastic syndrome is important because it could represent the early manifestations of an occult cancer, allowing diagnosis at an initial stage. We are reporting the case of a 62-year-old patient who was hospitalized in the Cardiology Clinic with clinical symptoms of deep venous thrombosis at the right lower limb. The diagnosis was confirmed by the imaging methods: venous echo doppler and phlebography. Catheter directed thrombolysis was performed, followed by conventional anticoagulant treatment with favorable response. The patient was also investigated etiologically but without a clear result. After one month, chest radiography revealed a suggestive image for lung cancer, which required thoracic CT and bronchoscopy with biopsy. These investigations confirmed the diagnosis of left pulmonary cancer with carinal invasion, of the scumamocellular type, with multiorganic secondary disseminations. The patient was directed to the Oncology Clinic. This case highlights the difficulty of making an etiologic diagnosis of deep venous thrombosis and a particular form of clinical onset of occult cancer. Since in the present case the occurrence of DVT preceded the diagnosis of the pulmonary cancer, the need to perform a screening of neoplasia is evident in case of any thromboembolic event occurring without an apparent cause, especially in the case of male patients. **Keywords**: PULMONARY CANCER, PARANEOPLASTIC SYNDROMS, DEEP VENOUS THROMBOSIS.

Paraneoplastic syndromes (PNS) represent a heterogeneous group of signs and symptoms associated with the progression of malignancy but not due to the direct

effects of primary tumor, adenopathy or metastasis (1). Recognition or diagnosis of a PNS is important because it could represent the early manifestations of an occult cancer, allowing diagnosis at an initial stage (2), can mimic metastatic disease and thus discourage the application of curative treatment for localized cancer, may also contribute to delaying treatment since complications of a cancer can be confused with a PNS (3). Cardiovascular paraneoplastic syndromes also include thrombophlebitis. Paraneoplastic thrombophlebitis (PNT) is one of the most suggestive manifestations under certain circumstances for cancer. They may be superficial and profound, occurring after the age of 50, more frequent in smokers and chronic alcohol users (4, 5, 6).

Venous thrombosis in patients diagnosed with malignant pathology is twice as high as patients without malignant pathology. Within this particular patient population, pulmonary cancer is the second in frequency regarding the relation with venous thrombosis second to hematological cancers (7, 8).

CASE REPORT

We are presenting the case of a 62-year-old patient, with no medical history of venous pathologies, who was a smoker until the age of 30 and an alcohol consumer, hospitalized in the Cardiology Clinic with clinical signs of edema in the lower right limb with hot tegument, erythema, pain in mole and functional impotence, suggestive for the diagnosis of deep venous thrombosis. The onset of the symptoms was 4 days prior. High-dose D-dimers (1,000-2,000 ng/mL) sustained the diagnosis.

The diagnosis was confirmed by imaging methods: venous echo doppler that revealed an almost complete thrombosis of the right femoral vein and almost complete venous thrombosis of the right popliteal vein. Phlebography of the right lower limb shows the opacity of the internal saphenous vein which communicates with the deep popliteal veins through the perforating veins. The femoral vein appears segmentally thrombosed, with dilated collateral muscular veins, with stasis and permeable anastomoses with the internal saphenous vein (fig. 1). The other veins were permeable.

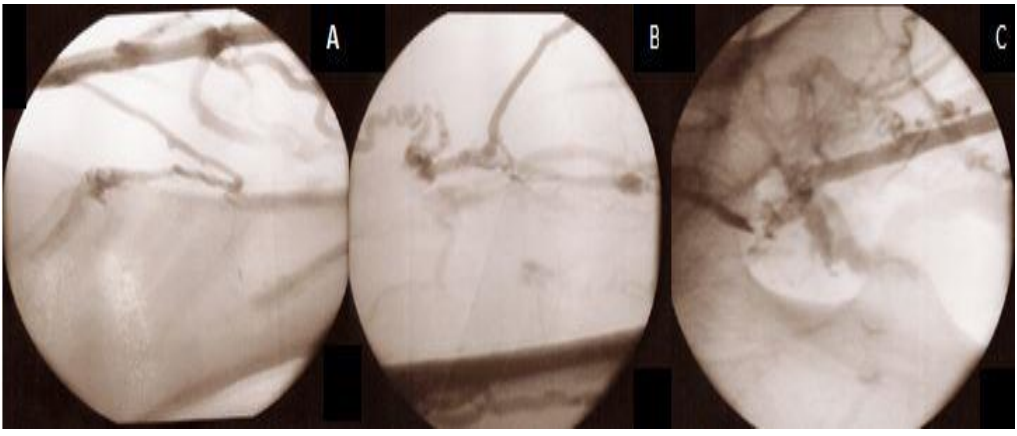

Fig. 1. A: Internal saphenous vein developing popliteal collateral circulation; B: Segmental thrombosis of femoral vein; C: The internal saphenous vein is still permeable throughout its entire length

Thrombolysis was subsequently conducted on the catheter with Rapilysin 1U/hr. followed by administration of Heparin 500 UI/hour. After 48 hours, phlebography showed reperfusion of calf veins in the upper 1/3 and femoral veins in the upper 1/3 of the thigh. The therapy was continued with conventional anticoagulant therapy (first heparin therapy, then oral anticoagulation) with favorable evolution.

At the same time, etiological investigations aimed at detecting a possible cause of deep venous thrombosis (DVT) were made, with the patient apparently not presenting prothrombotic risk factors (lack of varicose veins). Antiphospholipid antibodies were within normal range (Ig M = 10.3 U/mL, Ig G = 11.4 U/mL), and the thoracic radiography showed calcification of aortic knob; the suspicion of a possible type of alveolar filling syndrome arose although the patient was afebrile and did not have an inflammatory syndrome. Prostate ultrasound revealed a 21 mm hypoechogenic median node, but with negative prostate antigen, and upper digestive endoscopy revealed the presence of a hiatal hernia, corroborated with grade I esophagitis, atrophic gastritis in the corpus and fornix, and four inflammatory polyps with the diameter of 5- 10 mm.

Electrocardiogram showed the presence of a major left bundle branch block, echocardiography revealed dilated cardiomyopathy with moderate dilated ventricle with diffuse hypokinesia (FEVS 40%), normal valves, minimal valvular regurgitation.

The patient was discharged from hospital with oral anticoagulant medication and recalled a month later to resume etiological investigations.

After a month, the patient presented with influenced general state, effort dyspnea, cough, dysphonia and dysphagia. The right lower limb exhibited (up to the lower third of the thigh) petechial lesions, confluent in the lower half of the calf and which did not disappear in vitropress.

The blood pressure was 155/80 mmHg and the blood count showed an increased GGT (207 U/L), moderate leukocytosis (GA = 12,500/mm^3) associated with a fibrinogen of 4,64 g/L.

Thoracic radiography showed a larger predominantly enlarged mediastinum on the right; suprahilar adenopathy and a 2.7 cm round opacity in the middle left lung lobe, narrow tracheal lumen, which raised the suspicion of left bronchopulmonary neoplasia, requiring further investigations (fig. 2).

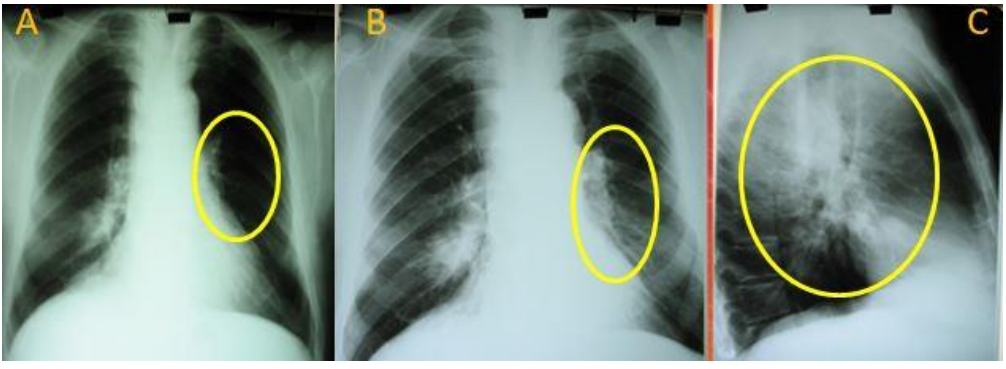

Fig. 2 A: initial posterior-anterior thoracic Rx, without changes in lung areas; B and C: postero-anterior thoracic and profile thoracic Rx after 30 days and presence of an opacity in the middle left lung lobe

The bronchoscopic examinations confirmed the diagnosis of pulmonary cancer into the left lung with the invasion of the tracheal carina. At the level of the left upper main bronchus a congestive infiltration process was observed, which interested the left primary bronchus from the origin and which then completely obstructed the inferior and superior left lobar bronchia. The bronchial biopsy revealed the mucosa with chronic inflammation and squamous metaplasia.

Computed topographies have been performed, confirming the presence of a 5.2/5 and 2/6 cm adenopathic tumor block, imprecisely delineated, located on the left primary bronchial emergence with posterior-lateral extension. The tumor was related anteriorly to the trachea, posteriorly to the esophagus, the vertebral body, the descending aorta and the azygos vein; medially is related to the mediastinal pleura, the medial wall of the main lower right bronchus and lateral to the right branch of the pulmonary artery (fig. 3). The interazigoaortic esophagus was almost occupied by a soft, non-homogeneous tissue mass with a cranial-caudal extension of about 6 cm, with the upper limit about 1 cm above the bifurcation of the trachea. The mediastinum was pushed to the left. There was another solid expanding formation of 2.5/3.0/1.0 cm in the topography of the right adrenal gland, hypodense after administration of the contrast substance. Another formation with the same characteristics was located on the left adrenal gland topography (1.5 cm).

Oncological consultation was required, and symptomatic cytostatic treatment was initiated. After the treatment, an improvement in dyspnea, coughing and dysphagia was noted. However, the progress of the diseases was rapidly progressive and ended with the patient's death 14 months after oncological treatment began.

The particularities of this case are the appearance of deep vein thrombosis as a first sign of a bronchopulmonary cancer in a paraneoplastic syndrome associated with the appearance of a scumamocellular carcinoma with a relatively rapid evolution of the tumor and of the adenopathies within one month to a current non-smoker. The association between the cardiovascular pathology, smoking and alcohol consumption - dilatory ethanolic cardio-myopathy, with such a brief clinical expression is also very rare.

DISCUSSION

Regarding thromboembolic events occurring in the neoplastic context, their incidence is 4 times higher than in the general population (9, 10, 11).

Nearly half of cases with migratory thrombophlebitis associate a neoplasia, and almost all of these are adenocarcinomas. Metastatic stages of cancers are associated with increased incidence of venous thromboembolism (12, 13, 14). Furthermore, chemotherapy increases the risk of venous thromboembolism 6 times than in the healthy population. Researchers (15) developed and validated a predictive model for the risk of venous thromboembolism (VTE) in patients undergoing chemotherapy (tab. I). The 0 score signifies a VTE risk below 1%, the intermediate score between 1-2% is associated with a 2% risk, and the score ≥ 3 signifies increased thrombotic risk (7%).

TABLE I

The risk of VTE associated with chemotherapy

Localization of neoplasia - Very high risk (stomach, pancreas) - High risk (pulmonary, lymphoma, urogenital)	 2 1
Pre-chemotherapy platelets ≥350 x 10^9/L	1
Hemoglobin <10 g/dL or the use of erythropoiesis growth factors	1
Pre-chemotherapy leukocytes > 11 x 10^9/L	1
Body Mass Index ≥ 35 kg/m^2	1

A percentage of 10-20% of VTE patients hide a malignancy and it is a predictive independent marker of death in these patients. Studies have also shown that approximately 10% of patients with apparently no cause of THP will develop a neoplasm over the next 5-10 years, most of which are detected within the first 1-2 years (16).

The combination of neoplasia - VTE decreases survival, thrombotic events being reported as the second cause of mortality in this category of patients. Neoplastic patients with VTE have a much higher risk of bleeding events under anticoagulant treatment but also recurrence of thrombotic events with the same or another location (17).

To evoke a paraneoplastic mechanism in a thrombophlebitis, a direct tumor mechanism (extrinsic compression, venous invasion) and other circumstances such as radiotherapy must be eliminated. Differential diagnosis should eliminate a disseminated intravascular coagulation syndrome, frequent in neoplastic pathology. Dysphonia in this patient is based on the damage of the infraglotic filter of the vocal tract (18) and the dysphagia is determined by the compression exerted by the tumor on the thoracic esophagus.

Causes may be related to increased expression of tissue factor, activator of extrinsic coagulation mechanism, indirect induction of tumor-induced cytokines on tissue factor expression, tumor excretion of cysteine proteinase as direct procoagulant trigger of X factor, independent of factor VII, inducing a state of relative resistance to protein C or direct action of the platelets by tumor membrane fragments.

Along with a thorough clinical examination and a careful history, the following are necessary: hematological balance, venous echo doppler examination, phlebography, pletismography, thoracic radiography, superior digestive endoscopy, computed tomography, tumor markers.

The main treatment is intravenous therapy with heparin or low molecular weight heparins, an important feature of paraneoplastic deep venous thrombosis being the lack of response to oral anticoagulants. In the case of anticoagulant medication contraindications, it is possible to use a filter on the inferior vena cava.

The rapid unfavorable progression represents a characteristic of neoplastic patients who suffer also from deep vein thrombosis (19).

CONCLUSIONS

Since in the present case the occurrence of DVT preceded the diagnosis of the pulmonary cancer, the need to perform a screening of neoplasia is evident in case of any thromboembolic event occurring without an apparent cause, especially in the case of male patients.

Clinica de Boli Infecţioase

RISK FACTORS FOR CARBAPENEMS-RESISTANT PSEUDOMONAS AERUGINOSA INFECTIONS(Abstract) : Since their introduction in clinical practice,carbapenems have been among the most powerfull antibiotics for treating serious infections cased by Gram-negative nosocomial pathogens,including *Pseudomonas aeruginosa*. The emergence of betalactamases with carbapenem-hydrolyzing activity is of major clinical concern.*Pseudomonas aeruginosa* is a leading cause of nosocomial infection. **Results** : Risk factors for colonization with carbapenems–resistant Pseudomonas in hospital are : history of *P. aeruginosa* infection or colonization within the previous year, (length of hospital stay, being bedridden or in the ICU, mechanical ventilation, malignant disease, and history of chronic obstructive pulmonary disease have all been identified as independent risk factors for MDR *P. aeruginosa* infection. Long -term -care facilities are also reservoirs of resistant bacteria. Risk factors for colonization of LTCF residents with resistant bacteria included age >86 years, antibiotic treatment in the previous 3 months, indwelling devices, chronic obstructive pulmonary disease, physical disability, and the particular LTCF unit. **Key words** : CARBAPENEMS –RESISTANT PSEUDOMONAS AERUGINOSA, RISK FACTORS, NOSOCOMIAL INFECTION, LONG -TERM CARE FACILITIES

Studiul de faţă, privind factorii de risc pentru infecţia cu *Pseudomonas aeruginosa* a fost efectuat pe 9 pacienţi diagnosticaţi cu acest tip de infecţie, internaţi în Clinica de Boli Infecţioase Iaşi în perioada ianuarie 2008 - septembrie 2010.

MATERIAL ŞI METODE

Pacienţii, 5 bărbaţi şi 4 femei s-au internat, cu o singură excepţie, prin transfer din alte servicii medicale şi au fost diagnosticaţi cu sepsis conform criteriilor ACCP/SCCM, şi cu disfunctii organice (tab. I).

REZULTATE

Toţi pacienţii prezentau comorbidităţi care au impus spitalizări prelungite în alte servicii medicale, chiar de terapie intensivă postoperator. Pacienţii cu vârsta peste 75 de ani erau diagnosticaţi cu demenţă senilă sau AVC vechi, soldate cu deficite neurologice. În cazul celorlalţi pacienţi notăm stenoză pulmonară infundibulară, tetraplegie spastică postfractură C5-C6, boală pulmonară cronică obstructivă şi peritonită biliară operată. În 4 cazuri erau purtători de sondă urinară a demeure (tab. II). Toţi bolnavii primiseră diferite asocieri de antibiotice in ultimele 3 luni, inclusiv cefalosporine de generaţia a III-a şi fluoroquinolone.

Pseudomonas aeruginosa rezistent la carbapeneme a fost izolat din 5 uroculturi (pacienţii 1,2,5,6,7), 2 hemoculturi (pacienţii 3,4), din escare (pacientul 8) şi din lichidul pleural (9). În toate cazurile s-a observat sensibilitatea la colistin şi rezistenţa la cefalosporine de generaţia a III-a, asocieri cu inhibitori de betalactamază, aminoglicozide,

fluoroquinolone şi carbapeneme. S-a iniţiat tratament cu colistin (în cazurile în care funcţia renală a permis acest lucru) în asociere cu vancomicină, clindamicină, carbapeneme, fluoroquinolone în funcţie de particularităţile clinico- paraclinice ale fiecărui caz. Evoluţia a fost favorabilă în primele două cazuri, bolnavul cu empiem a fost transferat în Clinica de Chirurgie Toracică pentru tratament de specialitate. Au decedat chiar în primele 24 ore pacientele cu hemoculturi pozitive cu *Pseudomonas aeruginosa* prin fenomene de şoc septic şi fibrilaţie ventriculară, acestea având şi cel mai mare scor APACHE II la internare (32, respectiv 38). Pacientul în vârstă de 14 ani, cu peritonită bilioasă operată, a fost diagnosticat cu sepsis cu stafilococ auriu Meti–R, bronhopneumonie, infecţie urinară cu *Pseudomonas aeruginosa*, asociind disfuncţie organică multiplă (insuficienţă respiratorie, renală, hepatică) şi decedează în a 14-a zi

de la internare. In cazul sau functia renala nu a permis utilizarea colistinului, singurul antibiotic la care tulpina de Pseudomonas era sensibila.

DISCUŢII

Rezistenta bacteriana este o problema in continua agravare in spitalele de pretutindeni. Desi in ultimii 20 ani s-a observat o incidenta crescuta a infectiilor asociate ingrijirilor medicala cu germeni gram-pozitivi, agentii patogeni gram-negativi continua sa se coreleze cu o rata crescuta a mortalitatii la acesti pacienti. Pentru ca posibilitatile terapeutice nu evolueaza de multe ori in acelasi ritm cu rezistenta bacteriana, masurile de preventie costituie constituie prima linie de aparare. Pseudomonas aeruginosa este unul dintre germenii cel mai frecvent incriminati in infectiile nozocomiale, fiind pe primul loc in etiologia pneumoniei in serviciile de terapie intensiva. Utilizarea excesiva a antibioticelor in spitale, a dus la emergenta tulpinilor de *Pseudomonas* cu rezistenta extinsa la antibiotice,inclusiv la noile generatii de betalactamine cu spectru extins, aminoglicozide si fluoroquinolone. (1) Carbapenemele au fost, pana recent, antibioticele de electie pentru tratarea infectiilor determinate de tulpini de *Pseudomonas aeruginosa* multidrog–rezistente. Totusi, *Pseudomonas* poate dezvolta rezistenta la carbapeneme prin variate mecanisme : scaderea permeabilitatii membranare, supraexpresia pompelor de eflux si productia de carbapenemaze. In rezistenta la betalactaminele cu spectru larg atribuita betalactamazelor sunt implicate mai ales metallo--betalactamazele (MBLs) : IMP, VIM, SPM and GIM. Metallo-betalactamazele hidrolizeaza carbapenemele si cefalosporinele antipseudomonas si nu sunt inhibate de inhibitorii de betalactamaze disponibili in acest moment.(2)

In Romania, conform studiului MAR-T derulat in patru centre universitare (Iasi, Constanta, Timisoara si Institutul „Matei Bals" Bucuresti) in perioada iulie 2008-decembrie 2009 sensibilitatea tulpinilor de Pseudomonas aeruginosa fata de ceftazidim s-a mentinut in proportie de 55,14%, nivelul activitatii piperacilina –tazobactam a fost de 57,88%, apropiata de cea a altor betalactamine, cu activitate anti-pseudomonas" iar pentru imipenem rata sensibilitatii a fost apropiata de cea a celorlalte betalactamine analizate : 57,12%, ceea ce infirma ideea activitatii sale superioare corelata cu utilizarea excesiva.Conform aceluiasi studiu, in perioada ianuarie- decembrie 2009 nivelul activitatii imipenemului si meropenemului a scazut sub 50%.(3)

Pe masura ce prevalenta P.aeruginosa multidrog –rezistent(MDR) a crescut de-a lungul ultimilor 20 ani, multe studii s-au concentrat asupra factorilor de risc specific asociati izolarii acestui agent etiologic. Desi datele variaza in literatura pornind de la insasi definitia multidrog-rezistentei se identifica : tratament anterior cu antibiotice, istoric de infectie sau colonizare cu P. aeruginosa in ultimul an, durata crescuta de spitalizare, internare in servicii de terapie intensiva, ventilatia mecanica, neoplaziile, istoric de boala pulmonara cronica obstructiva. (4) Factori de risc independenti pentru infectia cu Pseudomonas MDR au fost tratamentele anterioare cu cefalosporine, aminoglicozide si fluoroquinolone (prin alterarea ADN gyrazei,reducerea sau alterarea proteinelor membranei externe si a efluxului) si vancomicina (prin scaderea populatiei endogene gram-pozitive permite proliferarea P. aeruginosa). (5) Pacientii diagnosticati cu infectii cu Pseudomonas MDR sunt de obicei pacienti critici, cu spitalizari prelungite, tratati anterior cu multiple antibiotice cu activitate anti-pseudomonas. Toti cei 9 pacienti inclusi in studiul nostru aveau comorbiditati severe (deficite neurologice cu imobilizare la pat,escare multiple,diabet zaharat dezechilibrat sau interventii chirur-

gicale recente) implicand spitalizari prelungite in diferite servicii medicale, chiar in terapie intensiva post-operator. Istoricul tuturor a relevat date despre tratamenta anterioare cu antibiotice cu spectru larg, inclusiv cefalosporine de generatia a III-a si quinolone.Cel mai tanar pacient din lot a fost diagnosticat la aproximativ 10 zile post-operator cu Sepsis cu Stafilococ auriu meti –R si infectie urinara cu Psedomonas rezistent la carbapeneme cu evolutie fatala.

Serviciile de ingrijire a pacientilor pe termen lung (case de batrani, sanatorii, spitalele pentru bolnavii cronici) sunt de asemenea rezervoare de germeni rezistenti. Studii efectuate in Italia in aceste servicii medicale au indicat faptul ca 74,8% dintre rezidenti erau contaminati cu cel putin un germene rezistent, 64% cu germeni producatori de betalactamaze, 38,7% cu stafilococ auriu meticilino-rezistent (MRSA), 6,3% cu producatori de metallo-beta-lactamaze si 2,7% cu enterococ rezistent la vancomicina (frecventa colonizarii pacientilor din casele de batrani a fost mai redusa). Factorii de risc pentru colonizarea rezidentilor din serviciile de ingrijire pe termen lung cu bacterii rezistente au fost: varsta peste 86 ani, tratament antibiotic in ultimele 3 luni, dispozitive invazive, boala pulmonara cronica obstructiva, dizabilitatile fizice si specificul ingrijirilor iar pentru cei din casele de batrani au fost varsta si dementa. (6) Cele doua paciente diagnosticate cu sepsis cu P. aeruginosa,cu evolutie fatala in primele 24 ore erau internate pe termen lung intr-un serviciu de ingrijiri paliative respectiv in unul pentru boli psihice cronice indeplinindu-se conditiile de colonizare si infectie cu germeni rezistenti.

Rezidentii acestor unitati sunt vectori de transfer pentru bacterii rezistente in spitalele obisnuite, bacterii ce pot determina infectii atat in cazul gazdelor cat si al altor pacienti vulnerabili. P.aeruginosa poate supravietui timp indelungat in mediul de spital contaminand suprafete si surse de apa. Transmiterea de la un pacient la altul este posibila in conditiile nerespectarii riguroase a normelor de igiena. Tulpinile de Pseudomonas aeruginosa imipenem –sensibile pot fi transmise de la un pacient la altul si pot deveni rezistente la carbapeneme prin presiune antibiotica selectiva.(7) Colistinul a fost considerat terapia de salvare in infectiile cu BGN non-fermentativi, dar,conform studiului MAR-T, are o rata de eficienta in scadere ingrijoratoare.

CONCLUZII

1. Pseudomonas aeruginosa este unul din germenii cei mei frecvent incciminati in etiologia infectiilor nozocomiale, utilizarea pe scara larga a antibioticelor ducand la aparitia tulpinilor cu rezistenta extinsa la antibiotice, inclusiv la noile generatii de betalactamine cu spectru extins, aminoglicozide si fluoroquinolone.
2. Factorii de risc pentru infectiile cu Pseudomonas aeruginosa rezistent la carbapeneme sunt: spitalizarile prelungite, mai ales in servicii de terapie intensiva, ventilatia mecanica, dispozitivele invazive, tratamentele cu cefalosporine, quinolone, vancomicina.
3. Serviciile de ingrijire pe termen lung (de ingrijire paliativa, pentru pacientii cu afectiuni psihice cronice si chiar casele de batrani) sunt surse de bacterii cu rezistenta multipla la antibiotice.Intre cele doua tipuri de unitati spitalicesti exista un schimb continuu si un cerc vicios pentru transmiterea bacteriilor rezistente.
4. In studiu s-a observat ca singurul antibiotic la care au fost sensibile aceste tulpini de Pseudomonas a fost colistinul care, datorita nefotoxicitatii nu a putut fi folosit in toate cazurile.

NOUTĂŢI

Sindroamele confuzionale acute (delirium) din serviciile de terapie intensivă au o evoluţie defavorabilă sub tratament cu Rivastigmină

Un studiu multicentric randomizat dublu-orb contra placebo, efectuat în Noua Zeelandă, a inclus 440 de pacienţi, internaţi în servicii de terapie intensivă, care prezentau un sindrom confuzional acut (delirium), la care s-a administrat pe lângă tratamentul clasic cu haloperidol, şi rivastigmină, un inhibitor de colinesterază utilizat mai ales în boala Alzheimer, considerându-se că aceşti bolnavi pot prezenta o tulburare la nivelul neurotransmiterii colinergice. Studiul a fost întrerupt prematur de comitetul de securitate ca urmare a mortalităţii crescute observate în grupul celor trataţi cu rivastigmină (12 decese - 22%, faţă de 4 - 8% în grupul placebo ; $p=0,07$) În plus, rivastigmina a prezentat şi alte efecte nedorite : o durată mediană a sindromului confuzional de 5 zile, faţă de 3 zile în cazul administrării de placebo ($p=0,06$), cât şi o evoluţie mai severă a stărilor confuzionale sub rivastigmină, faţă de placebo, ceea ce a necesitat prescrierea unor doze crescute de neuroleptice şi de propofol pentru calmarea pacienţilor. A rezultat clar că rivastigmina nu numai că nu reduce durata sindroamelor confuzionale acute în terapia intensivă, dar este posibil să le prelungească durata şi chiar intensitatea. Schema de de tratament încercată a fost considerată inutilă şi periculoasă, rămânând a fi explicate bazele fiziopatologice ale acestui eşec terapeutic (Van Ejik M et al. Effect of rivastigmine as an adjunct to usual care with haloperidol on duration of delirium and mortality in critically ill patients : a multicentre, double-blind, placebo-controlled randomised trial. *Lancet* 2010 DOI : 10.1016/ S0140-6736(10)61855-7).

NEW CONCEPTS IN THE DIAGNOSIS AND TREATMENT OF IDIOPATHIC PULMONARY FIBROSIS (Abstract): Idiopathic pulmonary fibrosis is a chronic, progressive form of diffuse parenchymal lung disease, leading to respiratory failure. It has unknown causes, affects older adults, with a predilection for men, cigarette smokers, and it has a poor prognosis with a median survival time of approximately 2-3 years from diagnosis. Considering the rapid decline in lung function, this review brings into attention the importance of a multidisciplinary team for an early diagnosis. The methods for the assessment include spirometry which identifies restricted lung volume and impaired gas exchange, and imaging procedures. High-resolution computed tomography is the gold standard for the early diagnosis of idiopathic pulmonary fibrosis, allowing treatment initiation on mild-to-moderate form. Surgical lung biopsy is required in about a third of cases, in the lack of definite usual interstitial pattern on high-resolution computed tomography. The procedure is limited by its complications and increase mortality rate. At present, there are two antifibrotic therapies available for a mild-to-moderate form of idiopathic pulmonary fibrosis with positive effects on lung function but are not a cure. Other treatment options are lung transplant, pulmonary rehabilitation, stem cell therapy, and biotechnology. Mesenchymal stem cells could have protective effects, reducing inflammation and slowing fibrotic process. The review aims to illustrate the management of this rare disease and future directions for treatment research. **Keywords:** IDIOPATHIC PULMONARY FIBROSIS, MULTIDISCIPLINARY TEAM, ANTIFIBROTIC THERAPY, BIOTECHNOLOGY.

Idiopathic pulmonary fibrosis (IPF) is defined as a progressive diffuse parenchymal lung disease, leading to an irreversible decline in lung function of unknown etiology (1). IPF has a poor prognosis with a median survival time of approximately 2-3 years from diagnosis (2, 3). It is limited to the lungs, affects people in the later decades of life (IPF is rare before age 50) and is often initially misdiagnosed (4). IPF is a disease of the elderly and death rate increases with increasing age (5). Studies

have reported 3 million patients diagnosed with FPI, with a higher prevalence among men compared to women.

Etiopathogenesis

With the lung volumes reduced, patients are experiencing a decline in lung function, characterized by progressively worsening dyspnea (3, 6). Although IPF is still considered to be an idiopathic disease, some factors increase the risk of getting IPF. More than 70% of patients have a history of cigarette smoking (5). Studies reported that nonsmokers had a higher survival rate than former and current smokers. Other factors associated with lung injury are microbial agents (fungal, bacterial), gastroesophageal reflux, and having certain genetic predispositions (7, 8). Viral infections, such as hepatitis C virus, human herpesvirus-8, cytomegalovirus (9) and Epstein-Barr-Virus, were considered to be risk factors but this was not demonstrated (9). Many patients with IPF have comorbid conditions like sleep apnea (10, 11), diabetes mellitus, depression and pulmonary hypertension (10).

Histologically, the American Thoracic Society/European Respiratory Society (ATS/ERS) classification defines IPF as an entity of usual interstitial pneumonia (UIP) findings (12). IPF lungs have regions of normal lung parenchyma alternating with interstitial inflammation, fibrosis, and honeycombing (13). The IPF pathophysiology is not fully understood, but a repeated injury of alveolar epithelial type II cells (AECII) is considered a key factor (14). This leads to apoptosis, epithelial homeostasis is disrupted and finally, fibrosis occurs. Normal lung (rich in elastin) is replaced with an abnormal matrix rich in fibrillar collagen (15). Structural changes lead to multiple alterations of the alveolar-capillary membrane limiting the pulmonary gas exchange (16).

Diagnosis

The signs and symptoms lack specificity and resemble common lung diseases such as shortness of breath (exercise dyspnea), dry chronic cough, fatigue, unexplained weight loss, tiredness, aching joints and muscles, chest pain, finger clubbing. Dry, inspiratory bibasilar "Velcro-like" crackles can be heard when listening to the patient's lungs in over 80% of patients (17). This signs and symptoms of IPF can be mild or even absent early in the disease process but worsen over time.

The chest X-ray of a patient with IPF is initially normal but, after a while, it shows diffuse interstitial fibrosis associated with bronchiectasis and bullous emphysema described as honeycomb lung. Spirometry is one of the most commonly used tests of pulmonary function; it can be used to identify restricted lung volume and impaired gas exchange (18). Another lung function test is the 6-minute walk test (6MWT) which measures how far patients with IPF can walk in six minutes, how fast they exhibit exercise-induced oxygen desaturation and if they need supplemental oxygen therapy (19).

At present, high-resolution computed tomography (HRCT) is the gold standard for the diagnosis of UIP using standard criteria (20). Typical UIP pattern on HRCT is characterized by subpleural, basal predominance (21), reticular abnormality (22), honeycombing with or without traction bronchiectasis, and absence of non-UIP characteristics (23). Lester S. King (24) mentioned that "The history of medicine is the history of distinguishing one condition

from another." The difference between IPF ("idiopathic UIP") and "secondary UIP'' is very important because multiple diseases may be associated with UIP (25): collagen vascular disease (26), chronic hypersensitivity pneumonitis (27), drug-induced pulmonary fibrosis (28), desquamative interstitial pneumonia (29), respiratory bronchiolitis (30), asbestosis (31), sarcoidosis (32). Another problematic question is: How can we differentiate honeycombing between traction bronchiectasis and emphysema? A honeycomb lung in UIP can be regarded as being subpleural, predominant in the posterior and lower lobes, and a variable combination of thick-walled cysts (33). Emphysema appears with thinner walls and cystic airspaces located away from the chest wall (centrilobular/paraseptal emphysema) (34, 35). More extensive fibrosis and traction bronchiectasis on HRCT are often associated with increased risk of death (36). Presently, a certain UIP pattern on HRCT in a patient with typical clinical findings can define IPF without another investigations (22), like surgical lung biopsy or bronchoalveolar lavage (37). HRCT scan could help in the early diagnosis and treatment leading to a decreased decline lung function and mortality rate.

Surgical lung biopsy is required only in one-third of cases (in the lack of definite usual interstitial pattern on high-resolution computed tomography) due to the high risk of mortality and complications within the first 30 days after this procedure (38). The most common cause is an acute exacerbation of IPF, defined as a sudden acceleration of this disease and an increased mortality rate (39). Bronchoalveolar lavage is used to exclude other inflammatory disorders such as chronic hypersensitivity pneumonitis or eosinophilic pneumonia, but it is a nonspecific and insensitive method (40, 41). The current guidelines for the diagnosis and management of IPF do not recommend bronchoalveolar lavage in suspected IPF patients (42).

The diagnostic criteria for IPF include:

- exclusion of three other important causes of interstitial lung disease, like connective tissue disease, drug toxicity and long-term environmental exposures;
- a certain UIP pattern on HRCT;
- pulmonary biopsy for the lack of definite UIP pattern on HRCT (21).

Treatment

The ATS/ERS guideline for the pharmacological treatment of IPF includes two antifibrotic agents, nintedanib and pirfenidone. In the past, glucocorticosteroids and immunosuppressants were treatment options. Then, drug combinations were used: prednisone and azathioprine (43) or prednisone, azathioprine and N-acetyl-cysteine (NAC), but the latter combination proved to be harmful (44, 45). Triple therapy (prednisone, azathioprine and NAC) was excluded because PANTHER study (46) demonstrated an increased risk of death compared with placebo (45). Other molecules for the treatment of IPF that have been proposed and tested were interferon-ɤ, etanercept, vasodilators like bosentan, macitentan and ambrisentan, imatinib mesylate (a tyrosine kinase inhibitor), but no benefits were found (47). Bosentan, ambrisentan and macitentan are mentioned in the current guidelines for the treatment of pulmonary hypertension. Bosentan has proven its efficiency by increasing exercise capacity, right ventricular myocardial function and improving the symptoms but it can be hepatotoxic. It was

the first drug in the endothelin-receptor antagonist class. More ongoing studies have mentioned macitentan, another endothelin-receptor antagonist, as the last therapeutic option for pulmonary hypertension (48).

At present, nintedanib, an intracellular inhibitor of tyrosine kinases, is used for the treatment of IPF in US, Europe and Asia, slowing disease progression (49, 50). Pirfenidone, an antifibrotic agent, was approved in Europe in 2011. Pirfenidone and nintedanib were tested and approved in our country, both antifibrotic drugs showing benefits, with some differences between them. The adverse effects are dose depended and include gastrointestinal events, skin rash and photosensitivity. It has proven to reduce the decline in lung function during exercise, demonstrated by the 6-minute-walk distance (51). Nintedanib and pirfenidone can both reduce lung function decline but cannot cure the disease (52, 53). These therapies are indicated in a mild-to-moderate form of IPF (54). According to the TOMORROW (55) and INPULSIS (56) trials, nintedanib is superior to pirfenidone in terms of time to the first acute exacerbation of the disease (50).

Millan-Billi P and collaborators (57) mentioned the recombinant human soluble thrombomodulin as another treatment option. It has anti-inflammatory, antifibrotic and anticoagulant effects, and some studies have shown a decreased mortality rate. Presently, a phase three clinical study is underway (58). Other future treatments, like hemoperfusion with polymyxin B-immobilized fiber column and therapies against autoantibodies, are in the study (57). For IPF exacerbation cases, some theories argue that statins (59) and antacid treatment (60) have beneficial effects, but studies are needed to prove that. Follow-up and improving socio-economic factors may have a long-term risk reduction role, as with other chronic conditions (61).

We currently need alternative therapeutic options to reduce mortality and morbidity from IPF. The database of US National Institutes of Health includes 493 clinical trials of mesenchymal stem cells (MSCs), as a potential treatment for IPF. Different types of tissues, like bone marrow, adipose tissue, and umbilical cord blood can help us to obtain MSCs. Stem cells have been used in phase I clinical trials as a therapy for respiratory disease. Recent studies demonstrated that MSCs have protective effects, reducing inflammation and slowing the fibrotic process (62). The only ongoing study (a phase 1/2 trial) conducted in China, aims to isolate lung stem cells from patients' own bronchi. The stem cells will be processed in the laboratory and then the patients will receive the treatment in a single injection directly into the fibrotic lung zone. The first results of this trial are expected in December 2018, but the approval of such therapies will probably take several years (63).

IPF guidelines mention pulmonary rehabilitation as a therapeutic option for improving the quality of life in these patients (64, 65). Patients with severe disease may receive palliative care. Bajwah S and collaborators (66) suggest that patients appreciate conversations with the care team about IPF diagnosis and severity. Patients with depression symptoms can receive antidepressant drugs (62). The treatment option for end-stage IPF is lung transplantation which offers a long-term survival. Bajwah S and collaborators (66) mentioned that approximately 50% of patients with this rare disease are alive five years after

surgery for transplantation. Another problematic fact is the lung donor shortage compared to the high demand.

New treatment options were reported. Bioengineers from the State University of New York at Buffalo and the University of Toronto in Canada proposed a solution: lung-on-a-chip. This method is similar with microlithography, and it could make the drug testing process more efficient. Organ-on-chip technology is not only a more rapid method of drugs testing. The electronic chips can mimic the changes that occurs in the lung with IPF, reducing the number of tests performed on animals and lowering the costs of possible antifibrotic therapies. The researchers used pulmonary tissue produced in the laboratory and placed on chips, instead of semiconductor materials. This new method allows the lung-on-a-chip to expand and contract, like the real organ. Fibrosis has been induced by a protein that affects the lung cells (67).

CONCLUSIONS

Our research emphasized the importance of idiopathic pulmonary fibrosis as a progressive disease, with an increasing incidence. Two important aspects are essential for patients with this irreversible disease: an early and correct diagnosis, and the initiation of antifibrotic treatment as early as possible. IPF is a little-known disease, underdiagnosed, with a higher mortality rate than many forms of cancer. Equally important is teaching the population about the symptoms of this disease. Chronic dry cough and progressive dyspnea on exertion are the main clinical features. Over time, the disease limits the patient's ability to perform current activities. Patients often require supplemental oxygen. Diagnosis of IPF is difficult and thus we need a multidisciplinary team: pneumologists, radiologists and anatomo-pathologists.

We have mentioned that only two antifibrotic treatments are available for IPF. These drugs can reduce the decline in lung function, not decreasing the degree of fibrosis. We need more therapeutic options for IPF, but *in vitro* models are necessary to reproduce the development and progression mechanisms of lung scarring over time. Biotechnology represents a good method for testing new drugs, reducing the additional costs. Researchers from Buffalo University have found the solution: lung-on-a-chip.

Finally, patients with IPF need psychological support and care in palliative centers. The only treatment option left for end-stage IPF patients is a lung transplant.

Spitalul Clinic de Recuperare Iaşi
2. Secţia Clinică Medicală –Recuperare Respiratorie

METABOLIC PROFILE OF PATIENTS WITH CHOLESTEROL GALLSTONE DISEASE (Abstract): Metabolic syndrome is a clustering of cardiovascular risk factors as well as associated co morbidities, including cholesterol gallstones disease.The aim of our study is to prove the association between metabolic syndrome and cholesterol gallstones, to identify the main risk factors for this association and to trace the particularities of the metabolic syndrome in such patients. **Material and method:** Our cohort study enrolled 449 subjects, 312 patients diagnosed with metabolic syndrome and gallstones or cholecystectomy (group 1) and 137 patients diagnosed only with metabolic syndrome (group 2), hospitalized in the Respiratory Rehabilitation Medical Clinic between 2007-2009. **Results:** 85.25% of the patients with metabolic syndrome and cholesterol gallstones and 79.92% of the patients with metabolic syndrome alone had a body mass index (BMI) ≥ 25 Kg/m^2. Univariate and multivariate logistic regression were used to calculate the risk of gallstone disease associated with different metabolic syndrome variables. Waist circumference, BMI, fasting glycemia, insulinemia and insulin resistance index (HOMA-IR) registered statistical significant differences between the two study groups and were significantly associated with a higher risk of cholesterol gallstone as well as were blood pressure values ≥130/85 mmHg. The presence of 4 or 5 components of the metabolic syndrome increased the risk of gallstone disease by 3 times (OR = 3.3, $p<0.001$) compared to a 2 times higher risk (OR=2.1, $p=0.02$) in case of increased insulin resistance; there was no statistical significance for any of the lipid parameters. **Conclusion:** In our study, cholesterol gallstones appeared strongly associated with anthropometric measurements, fasting glycemia and insulin resistance index, as well as with the presence of metabolic syndrome as defined by the new clinical definition, despite the negative results for the lipidic components. These findings are consistent with the hypothesis that insulin resistance plays an important role in the pathogenesis and that cholesterol gallstone disease belong to metabolic syndrome.
Key words: INSULIN RESISTANCE, METABOLIC SYNDROME, CHOLESTEROL GALLSTONES

Sindromul metabolic a fost adus în prim-plan de Reaven (1988), sub denumirea de sindrom X, odată cu relevarea agregării, la o aceeaşi persoană, a unei constelaţii metabolice centrată de insulinorezistenţă: hiperinsulinism, hiperglicemie (scăderea toleranţei la glucoză sau diabet zaharat tip 2), dislipidemie aterogenă (hipertrigliceridemie, HDL-colesterol scăzut) şi hipertensiune arterială (1). Ulterior au fost adăugate o multitudine de alte componente, care alcătuiesc un tablou polimorf, ce include factori de risc cardiovascular tradiţionali şi nontradiţionali, precum şi condiţii patologice asociate diverse, cum ar fi litiaza biliară colesterolică (LBC), steatohepatita nonalcoolică

TABELUL I
Criteriile de diagnostic ale sindromului metabolic

Criterii	Valoare de referinţă
Perimetru abdominal crescut	>94 cm la bărbaţi şi >80 cm la femei
Hipertrigliceridemie (sau tratament medicamentos pentru scăderea trigliceridelor, ca indicator alternativ)	>150 mg/dL
HDL-colesterol scăzut (sau tratament medicamentos pentru creşterea acestuia)	<40 mg/dL pentru bărbaţi, <50 mg/dL pentru femei
Tensiune arterială crescută (sau medicaţie antihipertensivă)	Tensiunea arterială sistolică ≥130 mm Hg şi/sau diastolică ≥85 mm Hg
Glicemie bazală (à jeun) crescută (sau tratament medicamentos hipoglicemiant)	≥100 mg/dL

şi steatoza hepatică, sindromul ovarelor polichistice etc. (2,3).

De-a lungul timpului, au fost elaborate mai multe definiţii ale sindromului metabolic (SM), recent fiind publicate rezultatele unui consens al mai multor organizaţii, care recomandă pentru diagnosticul clinic prezenţa a minimum trei dintre criteriile prezentate mai jos (tab. I) (4).

Studiile epidemiologice au relevat ca factori de risc modificabili pentru LBC dislipidemia, obezitatea, în special cea abdominală şi diabetul zaharat. Se pare că hiperinsulinismul şi insulinorezistenţa reprezintă veriga de legătură între LBC, SM şi obezitatea propriu-zisă (5,6,7). Cercetări recente au indicat rolul modulator al unor receptori nucleari– receptorul farnesoid X (FXR), în conexiunile metabolice dintre acizii biliari, trigliceride, carbohidraţi şi rezistenţa la insulină; prin această mediere, se pare că se realizează o legătură la nivel molecular între litiaza biliară şi sindromul metabolic (8,9).

Pornind de la argumentele prezentate, obiectivele studiului de faţă sunt reprezentate de identificarea factorilor de risc pentru LBC în cazul pacienţilor cu SM şi evidenţierea celor cu cea mai înaltă semnificaţie statistică, prin utilizarea parametrilor clinici şi de laborator definitorii pentru SM (insulinorezistenţa, perturbarea metabolismului glucidic şi lipidic, hipertensiunea arterială) precum şi stabilirea particularităţilor sindromului metabolic în cazul pacienţilor cu LBC.

MATERIAL ŞI METODĂ

Profilul pacienţilor. S-a realizat un studiu de cohortă pe un număr de 449 pacienţi, internaţi în Secţia Clinică Medicală – Recuperare Respiratorie în perioada ianuarie 2007 – decembrie 2009. În funcţie de diagnosticul stabilit în urma evaluării clinico-paraclinice, pacienţii au fost împărţiţi în 2 loturi: lotul 1, format din 312 pacienţi cu sindrom metabolic şi LBC şi lotul 2, format din 137 pacienţi cu sindrom metabolic dar fără LBC.

Criteriile de includere a pacienţilor în cele 2 loturi au fost reprezentate de vârsta peste 18 ani, obiectivarea imagistică (ecografică sau prin tomografie computerizată) a litiazei biliare veziculare sau prezenţa istoricului de colecistectomie pentru litiază biliară, date sugestive de laborator.

Criteriile de excludere. Din studiu au fost excluşi pacienţii cu afecţiuni cunoscute că asociază litiază biliară prin mecanism hemolitic sau infecţios (ciroză hepatică alcoolică, infecţie virală B, D sau C, siclemie, proteze valvulare metalice, litiază coledociană sau intrahepatică); de asemenea, au fost excluşi din studiu pacienţii diagnosticaţi cu diabet zaharat franc, luând în considerare doar pe aceia care au prezentat glicemie < 126 mg/dL à jeun şi/sau < 200 mg/dL la 2 ore după administrarea pe cale

orală a 75 g de glucoză.

Parametrii analizaţi în prezentul studiu au fost reprezentaţi de indexul de masă corporală (IMC), circumferinţa abdominală, greutatea corporală slabă (*lean body weight*--LBW), suprafaţa corporală (*body surface area*-BSA), tensiunea arterială sistolică (TAS) şi diastolică (TAD), glicemia à jeun, colesterolul total, HDL-colesterolul, LDL-colesterolul, trigliceridele (TG), indexul de acumulare lipidică (*lipid accumulation product*-LAP), insulinemia bazală şi indexul de insulinorezistenţă (*Homeostasis Model Assessment of Insulin Resistance* - HOMA-IR). Nivelul insulinei bazale a fost determinat în 65 de cazuri prin metoda imunochimică de detecţie prin electrochemiluminiscenţă (ECLIA), iar indexul de insulinorezistenţă HOMA-IR a fost calculat după formula: HOMA-IR = insulinemia bazală (μU/mL) $\times$ glicemia à jeun (mmol/L) / 22,5. Indexul de acumulare lipidică (LAP), un nou parametru de evaluare a riscului cardiovascular, a fost calculat pe baza trigliceridemiei serice şi a perimetrului abdominal, diferenţiat pe sexe: (P abdominal 65) x TG la bărbaţi şi (P abdominal 58) x TG la femei.

Materialele de lucru au fost reprezentate de foile de observaţie clinică şi biletele de ieşire din alte servicii medicale, pe baza cărora s-au completat fişe de evaluare a pacienţilor, după obţinerea în prealabil a consimţământului lor informat.

Analiza statistică. Datele au fost analizate şi exprimate statistic descriptiv. Riscul de a dezvolta LBC în funcţie de prezenţa anumitor factori a fost evaluat cu ajutorul raportului cotelor şi regresiei logistice, după o prealabilă codare în formă binară a variabilelor continue. Prelucrarea statistică a fost realizată prin intermediul programului *Statistica 8.0*.

REZULTATE ŞI DISCUŢII

Lotul 1 a fost alcătuit din 312 pacienţi (248 femei şi 64 bărbaţi) diagnosticaţi cu SM şi LBC, iar lotul 2 din 137 pacienţi (91 femei şi 46 bărbaţi) diagnosticaţi cu SM dar fără LBC. Vârsta medie a pacienţilor nu a înregistrat diferenţe semnificative între cele 2 loturi ($64,21 \pm 11,67$ ani în cazul lotului 1 şi $62,25 \pm 10,45$ ani în cazul lotului 2). Repartiţia pe grupe de vârstă a pacienţilor cuprinşi în cele 2 loturi este redată în fig. 1.

Obezitatea şi statusul supraponderal au înregistrat o prevalenţă ridicată în loturile studiate, 85,25% dintre cazurile cuprinse în primul lot şi 79,92% dintre cele din al doilea lot având IMC $\geq$ 25 Kg/m^2.

Între cele 2 loturi au existat unele diferenţe statistic semnificative din punct de vedere al valorilor medii ale parametrilor

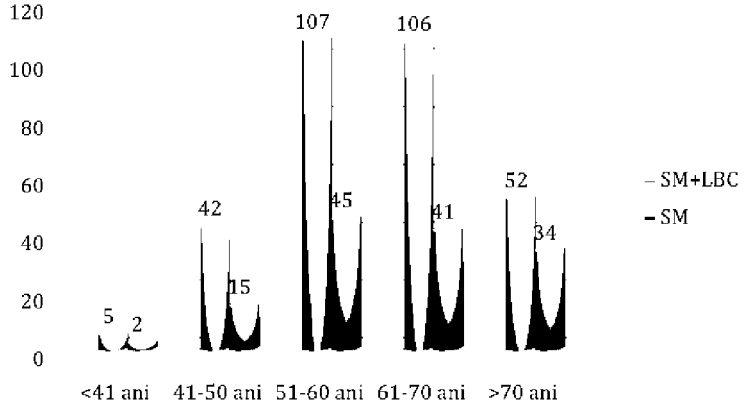

Fig. 1. Repartiţia pe grupe de vârstă a pacienţilor din cele două loturi

TABELUL II
Compararea valorilor medii ale parametrilor evaluaţi

	Medie lot 1	Medie lot 2	p
IMC	31,40	28,31	<0,001
LBW	48,33	49,11	NS
BSA	1,84	1,82	NS
Circumferinţa abd.	106,50	98,2	<0,001
Glicemie	109,62	103,47	0,02
Col total	201,17	197,53	NS
HDL	47,40	48,46	NS
LDL	124,18	125,52	NS
COL/HDL	4,36	4,28	NS
TG	142,65	137,85	NS
LAP	6694,49	6657,36	NS
Insulinemie bazală	9,56	8,67	0,05
HOMA-IR	1,30	1,20	0,03
TAS	131,7	128,5	<0,001
TAD	72,8	71,5	0,004

evaluaţi, după cum este redat în tab. II. Pacienţii cu SM şi LBC au prezentat valori mai mari ale IMC, circumferinţei taliei şi valorilor tensionale ; de asemenea, valorile glicemiei, insulinemiei bazale şi HOMA-IR au fost crescute, comparativ cu pacienţii diagnosticaţi doar cu SM, diferenţele fiind statistic semnificative.

Obezitatea şi statusul supraponderal (IMC ≥25 Kg/m^2), circumferinţa taliei, hiperglicemia, rezistenţa crescută la insulină (HOMA-IR >2,5) şi numărul de criterii din definiţia SM s-au asociat semnificativ cu un risc crescut de LBC.

Niciuna dintre variabilele ce evaluează metabolismul lipidic (colesterol total, HDL--colesterol, colesterol total/HDL, LDL-colesterol, trigliceride, LAP) precum şi unii indici antropometrici (greutatea corporală „slabă" şi suprafaţa corporală) nu s-au asociat cu riscul de LBC (tab. III).

Întrunirea a 4 sau 5 dintre criteriile SM

TABELUL III
Asocierea parametrilor evaluaţi cu probabilitatea de LBC

	Raportul cotelor	Interval de încredere	p
Sex	0,58	0,29-1,08	NS
Vârsta (F>55, M>45)	2,17	1,32-3,95	0,008
Circumferinţa abd. (F>80, M>94)	3,65	1,98-6,85	<0,001
IMC (?25)	3,02	1,57-6,12	<0,001
Glicemie (>100)	2,21	1,15-4,02	0,02
Trigliceride (>150)	1,12	0,57-2,15	NS
Col total (>190)	1,31	0,62-2,07	NS
LDL (>100)	1,15	0,71-2,24	NS
HDL (M<40, F<50)	1,18	0,55-2,42	NS
Col total/HDL	1,09	0,37-2,52	NS
3 criterii SM	8,57	2,56-29,91	<0,01
4 criterii SM	6,43	1,55-18,72	0,02
5 criterii SM	9,46	1,75-102,31	0,02
HOMA-IR (>2,5)	1,82	1,14-4,74	0,01
TAS >130 mmHg, TAD >80 mmHg	3,26	1,65-6,43	0,002

a determinat o creştere de peste 3 ori a riscului de LBC (OR = 3,3, p<0,001), iar rezistenţa crescută la insulină, o creştere de peste 2 ori (OR=2,1, p=0,02). Deoarece pacienţii de sex feminin şi cei vârstnici au înregistrat o pondere ridicată în loturile studiate, am ajustat riscul funcţie de cele două variabile, în cadrul regresiei logistice multivariate. Consecutiv acestei ajustări, SM a fost asociat în continuare cu o creştere de 2,9 ori a riscului de LBC iar rezistenţa crescută la insulină, cu un risc de 1,8 ori mai mare.

Am încercat analizarea unor parametri antropometrici suplimentari, cum ar fi compararea suprafeţei corporale şi a greutăţii corporale „slabe" între loturile luate în studiu, fără a se înregistra diferenţe statistic semnificative ; în schimb, IMC şi perimetrul abdominal au fost puternic asociaţi cu riscul de LBC (p<0,001), aşa cum arată şi datele din literatură (7,11).

În studiul nostru, încercarea de a găsi corelaţii între parametrii metabolismului lipidic şi litiaza biliară a eşuat, chiar şi pentru cei incluşi în definiţia sindromului metabolic : HDL-colesterolul şi trigliceridele serice, contrar datelor din literatură (12).

Insulinemia bazală şi glicemia bazală au avut valori semnificativ mai mari la pacienţii cu LBC şi SM iar indexul de insulinorezistenţă peste 2,5 a fost asociat cu un risc crescut de LBC (OR=1,82 ; p=0,01).

CONCLUZII

Studiul de faţă a avut rezultate similare cu cele din literatură în ceea ce priveşte asocierea litiazei biliare cu unii parametri antropometrici şi cu indicii de insulinorezistenţă, fiind discordant în ceea ce priveşte indicatorii dislipidemiei. În plus, au fost puternic asociate cu riscul de LBC valorile tensionale mai mari de 130/80 mm Hg, posibil şi în prezenţa unei multitudini de factori de risc comuni pentru boala cardiovasculară şi litiaza biliară.

Rezultatele obţinute capătă o relevanţă în plus dacă amintim că datele marilor studii epidemiologice privind litiaza biliară (NHANES III, MICOL) au obţinut asocieri mai puternice între parametri glucidici, insulinorezistenţă şi perimetrul abdominal mai ales la sexul masculin, în timp ce în lotul nostru de studiu au predominat populaţia feminină şi vârstnicii (5,13).

În concluzie, litiaza biliară colesterolică poate fi integrată în contextul sindromului metabolic, considerat de Grundy un factor de risc cardiovascular „multiplex", putând avea multiple semnificaţii : semnal, factor de agravare a prognosticului prin numeroase complicaţii şi implicaţii terapeutice, ţinând cont de faptul că medicaţia hipolipemiantă, indispensabilă pacientului cu sindrom metabolic, amplifică riscul litogen.

NOUTĂŢI

TELOCITELE DIN EPICARDUL UMAN

Studii de imunohistochimie şi imunofluorescenţă au demonstrat existenţa telocitelor în epicardul uman. S-a evidenţiat faptul că telocitele apar în epicard, acţionând drept celule doică pentru progenitorii cardiomiocitelor. Sunt caracterizate de prezenţa telopodelor-prelungiri celulare foarte lungi (zecimi de micrometri), foarte subţiri (0,1-0,2 micrometri), cu o configuraţie moniliformă. Telocitele epicardice interconectate creează reţele celulare tridimensionale, conectate cu reţeaua tridimensională a telocitelor miocardice ; în acelaşi timp, stabilesc legături spaţiale strânse cu capilarele sanguine miocardice şi cu terminaţii nervoase. Telocitele eliberează microvezicule sau corpi multiveziculari exocitotici în spaţiul extracelular. Fenotipul telocitelor umane epicardice este similar celui al telocitelor localizate printre cardiomiocitele umane. Rămane de stabilit rolul telocitelor în procesele de regenerare şi de reparare la nivel cardiac, precum şi în procesele patologice induse de inhibiţia lor funcţională sau de variaţia lor numerică. Telocitele, prin proprietăţile lor, ar putea asigura baza terapiei celulare în diverse afecţiuni celulare (Popescu LM, Manole CG, Gherghiceanu M, Ardelean A, Telocytes in human epicardium. *J Cell Mol Med* 2010 ; 14 (8) : 2085-2093).

DIABETUL ZAHARAT TIP II INDUCE MODIFICĂRI STRUCTURALE ŞI FUNCŢIONALE ALE MEMBRANEI ERITROCITARE

Un studiu prin spectroscopie FTIR demonstrează că valorile mari ale glicemiei pacienţilor cu diabet zaharat tip II afectează membrane eritrocitară. Atât proteinele cât şi lipidele membranei eritrocitare sunt afectate, apărând modificări ale structurii secundare tip b a proteinelor şi restricţii vibraţionale la nivelul interfeţei fosfolipidice. Modificările au apărut doar în cazul grupului de studiu cu valoarea medie a glicemiei de 285mg/dL, comparativ cu al doilea grup de studiu cu o valoare medie a glicemiei de 185mg/dL (Mahmoud SS. The impact of elevated blood glycemic level of patients with type 2 diabetes mellitus on the erythrocyte membrane : FTIR study. *Cell Biochem Biophys* 2010 ; 58 (1) : 45-51).

SECONDARY HYPERTENSION DUE TO PHEOCHROMOCYTOMA. CASE REPORT (Abstract): Pheochromocytoma, a rare endocrine tumor characterized by massive catecholamine secretion is found in less than 1% of patients with hypertension. We report the case of a 40-year-old patient who presented to the VIth Medical Clinic of the Iaşi Rehabilitation Hospital with discrete digestive and anxiety symptoms, normal blood pressure, without orthostatic hypotension and sudden paroxysms. The diagnosis was slightly late, with the random detection of clinical and biological changes. Laboratory tests detected a right adrenal tumor and twice the normal plasma and urinary metanephrine and normetanephrine levels confirmed the imaging diagnosis. Surgery and careful postoperative monitoring yearly, possibly for life, are key elements in the management of pheochromocytoma. Prior to surgery, the patient required treatment with alpha-blockers and nitrates to maintain normal blood pressure levels. **Keywords**: SECONDARY HYPERTENSION, PHEOCHROMOCYTOMA, ALPHA-BLOCKERS, SURGICAL TREATMENT.

Secondary hypertension (SH) is a relatively uncommon condition, accounting for about 5% of all potentially reversible hypertensive patients. The most common causes of SH are renovascular disease, aortic coarctation, pheochromocytoma, primary hyperaldosteronism, thyroid dysfunction and Cushing's syndrome. Of the causes of SH, more than half have endocrine causes (1, 2). Hyperaldosteronism is the major endocrine disorder that causes high blood pressure, followed by pheochromocytoma and Cushing's syndrome. When a patient is found to have high blood pressure, a comprehensive history and a complete physical examination are essential for detecting a possible cause of hypertension. Depending on the findings, additional screening and diagnostic studies may be required. Hypertension is a major cardiovascular risk factor with a continuously increasing incidence (3).

Pheochromocytoma is a rare endocrine tumor (less than 1% of patients with hypertension) of neuroectodermal origin, located in the medulla of the adrenal gland, uni- or bilateral, characterized by massive catecholamine secretion: adrenaline / epinephrine, noradrenaline / norepinephrine, dopamine, especially in people aged 40 to 50 years (4).

Despite technical progress in modern diagnostic methods and treatments for pheochromocytoma, early examination for the presence of this tumor remains the key for a best possible outcome in these patients. Timely diagnosis and appropriate treatment can prevent a wide variety of potentially

catastrophic cardiovascular complications (5). The effect on the cardiovascular system is mediated by membrane type α and β receptors, expressed by sustained elevated blood pressure or hypertensive crisis, accompanied by nonspecific symptoms such as pain, nausea, abdominal pain, coronary pain, dyspnea, visual disturbances, dizziness, tremor, anxiety. Differential diagnosis with migraine, panic attack, acute hypoglycemia, acute coronary artery disease, use of sympathomimetics, cocaine is essential (6). Modern biochemical tests should include tests that offer the best diagnostic performance available. In order to minimize the false positive test results, particular attention should be paid to pre-analytical and sampling conditions (7). Postoperatively, patients should be followed-up yearly for at least 10 years by measurements of plasma or urinary metanephrine for the timely detection of recurrent or metastatic disease. Patients at high risk for recurrence or metastatic disease (young age, multiple or large tumors, genetic background) should be followed-up lifelong (8).

CASE REPORT

A 40-year-old man residing in an urban area, approximately one-month smoke-free presented to our clinic complaining of epigastralgia, profuse sweating, nervousness, dizziness, headache, weight loss (7 kg in one year), symptoms that occurred 6 months earlier. Objective physical assessment revealed moderately influenced general health status, afebrile, no changes in respiratory system, tachycardia (100/minute), rhythmic heart sounds, no heart murmurs, normal blood pressure (120/80 mmHg), slight sensitivity to palpation in the right hypochondrium, bilateral nystagmus. Neurological consultation did not reveal any focal signs, nystagmus being considered congenital. From the biological point of view, hematologic profile, renal function, liver function and blood electrolytes were within the normal range. Of the investigated tumor markers increased levels (8.58 ng/ml) were found only for the carcinoembryonic antigen. Endocrine assessment revealed normal thyroid hormone levels and thyroid ultrasound normal plasma ACTH and cortisol levels. Abdominal ultrasound revealed enlarged right adrenal gland (78/73/73 mm) with a non-homogeneous structure transonic area inside and Doppler signal present, mass compressing the vena cava and coming in contact with the portal vein (fig. 1).

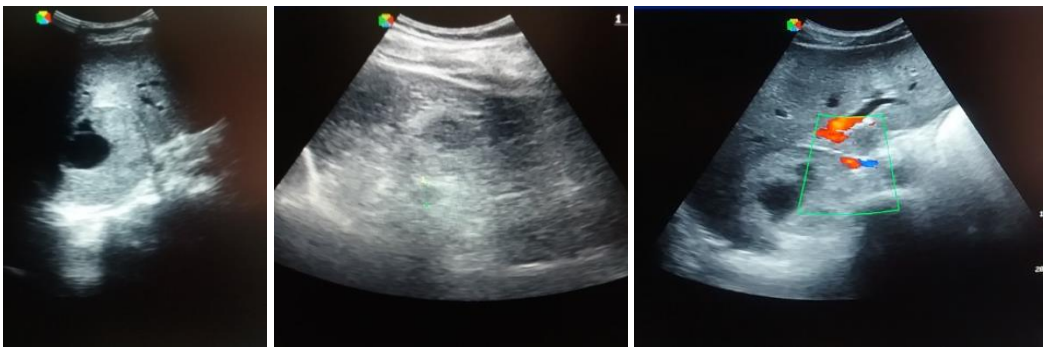

Fig. 1. Abdominal-pelvic ultrasound - enlarged adrenal gland with a non-homogeneous structure with transonic areas inside and present Doppler signal

As to the biochemical diagnosis of the adrenal gland tumor, the measurement of plasma and urinary metanephrines and normetanephrines (catecholamine metabolites)

is the most sensitive method (9). A firm diagnosis was made based on levels exceeding twice the upper limit of normal. Determination of urinary vanillylmandelic acid has currently a rather historical value.

Electrocardiogram on admission showed sinus rhythm, 78 beats/minute, without significant morphological changes. Echocardiography did not reveal appearance of catecholamine cardiomyopathy. The patient was monitored with ABPM, the following being recorded: systolic blood pressure between 106 and 149 mmHg and diastolic pressure between 54 and 99 mmHg, with a maximum heart rate of 124 beats/minute at noon; heart rate ranged from 71 to 124/minute.

In making a correct diagnosis it was necessary to complete the radiological investigations with an abdominal computed tomography. In the upper abdomen, a bulky right adrenal tumor was described, with no clear-cut cleavage with the posteroinferior surface of the liver, with vascular elements of the liver and right renal hilum and inferior vena cava, respectively.

DISCUSSION

By corroborating clinical and laboratory data, the final diagnosis was pheochromocytoma (based both on ultrasound and computed tomography findings and high levels of catecholamine metabolites). Useful for this purpose would have been serum chromogranin A measurement and 1 mg dexamethasone suppression test with cortisol sampling, considering the normal fasting ACTH and cortisol levels, but they could not be performed.

In the presented case differential diagnosis was necessary given the unusual onset and course. Of the included differential diagnoses we mention the following:

- Hyperthyroidism: thyrotoxicosis with intense sweating, weight loss, tachycardia, irritability, nervousness; counter-arguments - euthyroid status, thyroid ultrasound without pathological changes, a number of symptoms of thyrotoxicosis overlap with those caused by pheochromocytoma;
- Angina pectoris was included due to epigastralgia, taking into account the risk factors: smoker with a slight tendency to hypercholesterolemia (total cholesterol 220 mg/dL), presenting sinus tachycardia; counter-argument – electrocardiogram without terminal phase changes (broad T wave but <1/2 R wave) in crisis, normal thoracic radiography, echocardiography without changes in left ventricular kinetics;
- Insulinoma: adrenergic symptoms - weakness, excessive sweating, tachycardia; counterargument: normal blood glucose (82-87 mg%);
- Anxiety disorders (panic attacks) (10).

When diagnosing a patient with pheochromocytoma, the only curative treatment is laparoscopic surgical removal. Surgical intervention is much riskier than in the case of any other non-catecholamine-secreting tumor of similar size. The goal is to destroy the source of catecholamines and to neutralize the effects of their excess.

Extremely important is preoperative antihypertensive medication, initiated about 1-2 weeks before surgery. The treatment of choice in our case was alpha-blockers (prazosin, phentolamine). Calcium channel blockers and nitrates can also be used, preventing coronary spasm and catecholamine-induced myocarditis. Note that the isolated use of β-blockers may induce tensional paroxysm because of the loss of the vasodilatory compensatory effect induced by the stimulation of vascular β-receptors. Thus, β blockers are not used in case of SH onset if an endocrine etiology is suspected (11).

In our case, the patient received both nonpharmacological (volemic repletion) and

pharmacological treatment with alpha-blocker (Cardura (Doxazosin) 1 mg/day), monitoring blood pressure and heart rate to prevent possible incidents that might have occurred intraoperatively. The evolution during hospital stay was good, constant, with normal, repeatedly measured blood pressure levels, including the ones on the ABPM monitoring.

CONCLUSIONS

The particularity of the case is given, first of all, by the unusual onset symptoms in a young individual with constantly normal blood pressure, without orthostatic hypotension and sudden paroxysms. The diagnosis was slightly late, with the random detection of clinical and biological changes. The associated symptoms were headache, profuse sweating, tachycardia, anxiety, hyperexcitability, abdominal pain, weight loss. Also, an important aspect of this case was the absence of complications, namely hypertensive retinopathy, hypertensive nephropathy, stroke, hypertensive encephalopathy, acute pulmonary edema, catecholamine cardiomyopathy, hypotension and shock, intratumorally hemorrhage or aortic dissection aneurysm.

Surgical treatment and careful yearly, possibly lifetime postoperative follow-up are key elements in the management of pheochromocytoma. In their absence, the prognosis is very poor. It is important to note that the endocrine etiology of SH should be considered in case of treatment resistance.

THERAPEUTIC ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY FOR CHOLEDOCHOLITHIASIS IN PATIENTS 80 YEARS OF AGE AND OLDER: EFFICACY AND SAFETY (Abstract): Choledocholithiasis is common in octogenarians and open surgery for its treatment has high operative risks. Thus, therapeutic endoscopic retrograde cholangiopancreatography (ERCP) has become the method of choice for management of such patients. The aim of this study is to evaluate the efficacy and safety of therapeutic ERCP for choledocholithiasis in octogenarians. **Patients and methods:** Data of 2325 patients who underwent therapeutic ERCP for choledocholithiasis from January 2014 to December 2018 was reviewed. Out of these, 222 patients were 80 years or older (study group) and the assessment of efficacy and safety of therapeutic ERCP was compared to that of 260 patients aged 51-60 (control group) randomly selected during the same period. Patient demographics, laboratory parameters, complications of the procedure, as well as post ERCP outcome were carefully reviewed in both groups. **Results:** The elderly group had a significantly higher incidence of comorbidities that the younger group (85.6% *vs.* 68.5%). Common bile duct cannulation was successful in approximately 84% of patients in both groups. The rate of ERCP-related complications was different in the two groups. The rates of pancreatitis particularly were significantly lower in the elderly compared to the younger patients (2.7% *vs.* 9.2% p=0.037). Procedure related mortality was zero in both age groups. Furthermore, successful stone extraction was not significantly different between the two age groups. **Conclusions:** Therapeutic ERCP for choledocholithiasis is an effective and safe procedure in patients 80 years of age and older, comparable to its use in those younger than 60 years of age.
Keywords: ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATO-GRAPHY, CHOLEDOCHOLITHIASIS, EFFICACY, SAFETY.

Life expectation has increased over the last 2-3 decades worldwide, and consequently, the number of elderly population is growing steadily (1,2). With advancing age, the risk of choledocholithiasis is increased, and complications of this disorder have led to a high mortality rate (3, 4). Moreover, surgery for its treatment is characterized by high surgical morbidity and mortality rates (5, 6).

Endoscopic retrograde cholangiopancreatography (ERCP) is one of the most important advances in the treatment of choledocholithiasis and it is now recognized as the first choice and gold standard procedure for the therapy of choledocholithiasis (7, 8). It is therefore understandable why therapeutic ERCP procedures are increasingly required in elderly patients with choledocholithiasis. However, therapeutic ERCP remains the riskiest routinely used endoscopic procedure, associated with several complications such as pancreatitis, bleeding, perforation and overall post-procedural mortality which are expected to have a higher incidence in elderly patients because of multiple and severe comorbidities (1, 8). Nevertheless, several studies reported the safety and efficacy of therapeutic ERCP in patients age 80 years and older diagnosed with choledocholithiasis, with a success rate and adverse events comparable to those found in younger patients (2, 4, 9-11).

The aim of this study was to evaluate the efficacy and safety of therapeutic ERCP in patients aged 80 years and older with choledocholithiasis.

PATIENTS AND METHODS

Patients

Between January 2012 and December 2018, a total of 2,325 patients underwent therapeutic ERCP for choledocholithiasis at the Institute of Gastroenterology and Hepatology, "Sf. Spiridon" County Clinical Emergency Hospital of Iasi, Romania. Patients were divided in two groups: octogenarians – the study group (defined as all patients aged 80 years or older) consisting in 222 patients, and a population of younger patients – the control group (a randomly selected cohort of patients aged between 51 and 60 years old, who underwent therapeutic ERCP during the same period) consisting in 260 patients.

Entry criteria included adult patients undergoing therapeutic ERCP for choledocholithiasis. Exclusion criteria were presence of ongoing or past acute pancreatitis, inability to perform proper follow-up, presence of additional risk factors for pancreatitis, and bleeding, history of previous ERCP, the need for reintervention or surgery during the same admission.

All past medical records together with periprocedural clinical and laboratory parameters, imagistic findings (ultrasonography and/or magnetic resonance cholangiopancreatography (MRCP)) and endoscopy reports were analyzed retrospectively. All patients were hospitalized and underwent before therapeutic ERCP routine hematologic and biochemistry testing, abdominal ultrasound, abdominal computed tomography or MRCP evaluation. The diagnosis of choledocholithiasis, with or without the presence of concomitant gallstones was confirmed by ultrasonography, MRCP or computed tomography, and all patients were hospitalized for at least 48 hours after therapeutic ERCP to assess the post-procedure complications. All patients signed an informed consent prior to therapeutic ERCP.

Methods

Endoscopic procedures were performed by 3 experienced endoscopists in therapeutic ERCP, using a standard duodenoscopes (TJF 160 Series Olympus, Japan). All patients were given topical pharyngeal anesthesia with lidocaine 10% spray, and endoscopic procedures were performed under sedation with intravenous midazolam and/or propofol (either alone or in combination) administered by a specialist in anesthesiology. Blood pressure, heart rate, ECG, and peripheral oxygen saturation (pulse oxime-

try) were continuously monitored. All patients were administered oxygen through a nasal cannula during the endoscopic procedure. Most frequently the procedures included endoscopic sphincterotomy alone, balloon dilatation was used only in few cases. Stone extraction was attempted by means of a balloon catheter, and/or Dormia basket, and only in difficult cases by endoscopic mechanical lithotripsy. At the end of each procedure a NSAID suppository (diclofenac 100 mg) has been administered to all patients.

Data collected included age, gender, significant comorbidities (classified as cardiovascular (e.g., hypertension, ischemic heart disease), metabolic (e.g., diabetes mellitus), pulmonary (e.g., chronic obstructive pulmonary), renal or cerebrovascular diseases), complete laboratory panels, endoscopic findings (anatomy of the papilla, periampullary diverticulum, cannulation success rate, stone clearance rate), ERCP-related complications such as post-ERCP pancreatitis, bleeding, cholangitis and perforation, all defined according to published criteria by Cotton *et al*., according to the lexicon for endoscopic adverse evolutions published by Cotton *et al*.; early mortality was defined within 30 days after the procedure.

Statistical analysis was performed with the *SPSS 16.0* software. *Chi-Square* (X^2) and p values were calculated and subsequently Odds Ratios (OR) were issued and compared for specific events.

TABLE I

Baseline therapeutic outcomes and ERCP – related complications

Parameter	Age >= 80 years		Age between 51–60 years		X^2 / p	OR		
	n	%	n	%		Value	95% confidence level	
							lower	upper
Concomitant gallbladder stones	40	36.0	59	45.4	2.162 / 0.141	.678	.403	1.139
Previous cholecystectomy	33	29.7	56	43.1	4.580 / .032*	.559	.327	.955
Concomitant chronic diseases	95	85.6	89	68.5	9.723 / .002*	2.735	1.434	5.219

Bleeding	0	0.0	8	6.2	7.065 /.008			
Acute cholangitis	0	0.0	4	3.1	3.473 /.062			

*Statistically significant data

RESULTS

The mean age of the study group was 84 (range: 80-98 years old) and the number of female patients was significantly higher in both groups. Baseline therapeutic outcomes and ERCP-related complication rates of the studied groups are shown in first table. Presence of concomitant gallbladder stones

was non-significantly higher in the control group, but history of previous cholecystectomy was significantly less frequent in octogenarians, compared to younger patients (33% *vs.* 56%, p = .032). More than two thirds of elderly patients had concomitant chronic diseases (mainly cardiovascular), significantly more compared to only one third in control group (85.6% *vs.* 68.5%, p = .002). Periampullary diverticula were significantly more frequent in the elderly group (25.2% *vs.* 14.6%, p = .038). There was no significant difference between the two age groups regarding rate of cannulation success (83.8% in both groups). Although not statistically significant, complete stone clearance rates were higher in the study group (71.2% *vs.* 66.2%).

Overall, the ERCP-related complications were less frequent in control group than in study group (2.7% *vs.* 18.5%, NS), as shown in first table. The most common complication was post-ERCP pancreatitis. Interestingly, there were only three cases of post-ERCP pancreatitis in elderly patients. Post-sphincterotomy bleeding occurred in no patient in the study group but in 5.4% of the control patients. In all cases it was easily managed endoscopically by injection therapy. There was also no perforation in both groups. Post-ERCP cholangitis occurred in no patient in the study group and in 2.7% of the control patients. There was no death related to the procedure in both age groups.

DISCUSSION

Life expectation has increased over the last 2-3 decades worldwide and subsequently, the number of elderly population is growing steadily (1-4). With advancing age, the risk of choledocholithiasis is also increased (1, 2, 4, 9). Clearly, the need for ERCP in the management of choledocholithiasis will become age dependent. However, therapeutic ERCP is an invasive method, associated with complications, which may have a higher incidence in elderly patient because of the presence of multiple comorbidities (1, 8, 13, 14). Nevertheless, several studies have reported that therapeutic ERCP for choledocholithiasis is comparable in terms of efficacy and safety between elderly (≥ 65 years of age) patients and younger ones (< 65 years of age) (1, 3). It should be underlined that "elderly" patients have been defined in most studies as those patients aged 65 years or older and only few studies were conducted on patients over 80 years old (4, 9, 10, 12).

The results of our study show that therapeutic ERCP is a successful and safe therapy method for choledocholithiasis in octogenarians, even safer than that performed in younger patients. Similar results were obtained in other previous studies that included patients aged 80 years or older (1, 4, 9, 10, 12, 13). Most studies indicate that despite the significantly greater number of comorbidities in octogenarians, the procedure-related complications rates were not significantly different compared to the younger group. Moreover, in the current study procedure-related complication rates were lower in the octogenarian group than in the younger group. Not significantly different complication rates between the age groups were reported in several other studies (2, 4, 9, 10, 12, 13, 15).

Comparable cannulation rates between the age groups are reported in many of the similar studies to date (2, 15, 16, 17). Despite an important incidence of juxtapapillary diverticula, not only cannulation rates but also complete bile duct clearance are

similar and consistent with widely reported rates in both groups.

Complication rates in our study are comparable to those reported in the literature both in octogenarians (2, 16-19) or in younger patients. Post-ERCP pancreatitis (PEP) is the most common complication, with reported prevalence ranging from 1.3% to 8% (1,2,19,20). Interestingly, Finkelmeier *et al*. (21) found PEP rate is significantly lower in patients above 80 years old. Recently, Han *et al*. (1) reported that PEP occurred in only 1.3% of octogenarians compared to 2.9% of youngers, probably due to changes in pancreatic histology leading to pancreatic atrophy with age that has been traditionally cited (22, 23). As stated, our study shows that the rate of PEP was lower in octogenarians (4.1%) than in youngers (12.3%) and all were mild disease, a finding reported in other studies (2) and explained by a decline in pancreatic exocrine function with aging (24). Therefore, age is considered by some authors to be a protective factor for the development of PEP (9). To be stressed is that in our study all PEP, independently on the age group were mild cases that did not prolong the hospitalization period more than 48 hours. Bleeding incidence was also in line with those reported in literature from 0.6% to over 2% (1-3), with a smaller prevalence in the elderly group. Similar results were obtained also regarding the post-ERCP cholangitis rates which were identified in isolated cases, the same as in current studies (1, 25). Consequently, as part of the literature suggests, perforation rates and procedure related mortality are of a scarce incidence, reported only in isolated cases (15). Some other previously published studies reported procedure-related mortality in the elderly from 0.6% to 1.6% (19).

CONCLUSIONS

Our study has several limitations: the single center distribution, it's retrospective methodology and the fact that the efficacy and safety of therapeutic ERCP for choledocholithiasis were compared only between two age groups (80 years or older and 51-60 years old), while patients ≤ 50 years and those between 61-79 years were not included. Despite these potential down sides, this study shows clearly that therapeutic ERCP for choledocholithiasis can be successfully and safely performed on patients aged 80 years or older.

THERAPEUTIC RESPONSE TO PEG-INTERFERON PLUS RIBAVIRIN IN CHRONIC HEPATITIS C (Abstract): **Aim** To evaluate the epidemiological, clinical-biological, therapeutic and evolutive characteristics of HCV-infected patients admitted in Hospital of Infectious Disease "Sf. Parascheva" Iaşi between 2012-2017. **Material and methods**: 408 patients received peginterferon alfa-2a/alfa-2b plus ribavirin for 48 weeks. Clinical and laboratory data were assessed at baseline, week 4, 12, 24, 48 (end of treatment, EOT), and 24 weeks after therapy (sustained virological response, SVR). **Results**: The mean age of patients was 48.78±11.30 years old (range 18-75 years), most patients being female (63.5%). Ten (2.5%) patients had co-infection with hepatitis B virus (HBV), and in 14 (2.1%) IL28B polymorphism was determined. Of the 408 patients receiving PEG-IFN α and ribavirin, 35% had SVR, but 22.8% had relapses and 36.3% were non-responders. The most common side effects were leukopenia (26.2%), followed by thrombocytopenia (21.4%), anemia (17.9%) and neutropenia (12.6%). **Conclusions**: The SVR rate in the studied group was only 35%, this fact demonstrates the need for new antiviral therapies, especially in patients with advanced fibrosis. **Keywords:** HCV, PEG-INTERFERON, RIBAVIRIN.

Viral hepatitis is important challenge in infectious pathology due to high incidence of the acute infections, risk to develop chronic infections and severity of these infections and also costs associated to the disease.

Chronic hepatitis C viral (HCV) infection is the main cause of hepatic cirrhosis, hepatocellular carcinoma and liver-related mortality in developed countries. Even if the disease has a major importance on morbidity and mortality, its natural history of the disease is not completely known. Chronic hepatitis C is a slowly progressive infection characterized by persistent hepatic inflammation which develops cirrhosis in 10-20% cases in 20-30 years (1).

HCV is an important cause of chronic liver disease both in Romania and worldwide. There has long been evidence that hepatitis C can lead to persistent infection in a large proportion of infected individuals, and may develop toward chronicization, cirrhosis, and hepatocellular carcinoma (2).

The most efficient initial therapy in HCV infected patients was interferon alpha-2b plus ribavirin for 24 or 48 weeks. Addition of one molecule of polyethylene glycol to interferon lead to a new biologically active molecule with longer half -life which allowed one weekly administration (3).

Peginterferon alpha plus ribavirin were the gold standard of HCV infection treatment for more than one decade, and its effectiveness was carefully monitored using accurate and sensitive techniques of molecular biology.

MATERIAL AND METHODS

The aims of our study were to evaluate the epidemiological, clinical-biological, therapeutic and evolutive characteristics of HCV-infected patients admitted in Hospital of Infectious Disease "Sf. Parascheva" from Iaşi between 2012-2017.

Ethical approval. The study was carried out according to Declaration of Helsinki 2008, and the International Ethical Guidelines. The study was approved by the Ethics Committee of the Infectious Diseases Hospital "Sf. Parascheva" from Iasi.

Patients and treatment. Eligible patients were included according to the criteria established by Romanian National protocol approved for HCV infection treatment, as follows: treatment naïve or experienced patients aged over 18 years with HCV genotype 1 infection, liver enzymes increased or normal, detectable RNA hepatitis C virus, liver biopsy, Fibromax test results: A ≥1, F ≥1 and /or S≥1 and Fibroscan results > 1.

Exclusion criteria were decompensated liver cirrhosis, mental illness, decompensated diabetes, neurological disease, autoimmune disease, coronary ischemic disease or uncontrolled severe heart failure, severe, uncontrolled respiratory disease.

Patients with HCV genotype 1 infection received 48 weeks of treatment with one of the following regimens: peginterferon alfa-2a at a dose of 180 μg per week plus ribavirin at a dose of 1000 to 1200 mg per day, or peginterferon alfa-2b at a standard dose of 1.5 μg per kilogram of body weight per week plus ribavirin at a dose of 1000 to 1200 mg per day. Treatment administration was in accordance to the approved Summary of Product Characteristics.

Patients evaluation. Clinical data related to gender, age, treatment history and comorbidities were collected at baseline. According to protocol, laboratory data included HCV RNA level, determination of genotype and sub genotype, alanine aminotransferases, HBsAg, anti-HIV antibodies, hemoglobin, platelets, leukocytes, neutrophils and IL28B polymorph/ism. Serum HCV RNA levels were measured with the Cepheid GeneXpert system (Cepheid, Sunnyvale, CA) with a lower limit of quantification and detection of 15 IU/mL. The degree of liver fibrosis was evaluated based on Fibromax / Fibroscan test, or liver biopsy.

HCV RNA was measured before treatment initiation, after 4 weeks of therapy and was repeated after 12 weeks in case of detectable viremia at 4 weeks. Measurement was repeated at 24 - weeks after treatment in cases when negativity test was not obtained, but a decrease of ≥ 2 log10 HCV RNA was found after 12 weeks of treatment, at end - of treatment (EOT) and 24 weeks after EOT. Biological measurements were performed at baseline, at week 4, 12 and 24 of treatment.

Outcomes. Effectiveness of therapy was assessed by the percentage of patients achieving sustained virologic response (SVR, defined as HCV RNA below the limit of detection 24 weeks after the EOT). According to the protocol, therapeutic failure was defined as detectable HCV RNA at

EOT. Relapse was considered detectable HCV RNA at SVR in patients with undetectable viremia at EOT.

Statistical analysis. The data were centralized in a *SPSS 18.0* database and processed with the statistical functions to which they are expected, at the significance level of 95%. Continuous variables were reported as a mean ± standard deviation, while categorical variables are reported as frequencies and percentages.

RESULTS

Patient characteristics

Between 2012 and 2017, 408 patients with chronic HCV infection were treated with peginterferon alfa-2a/alfa-2b plus ribavirin in our clinic. Most cases were observed in 2012 (243 cases), subsequently, a downward trend was observed, with only 22 cases in 2017 (fig. 1). The mean age of patients was 48.78±11.30 years (range 18-75 years), most patients being female (63.5%).

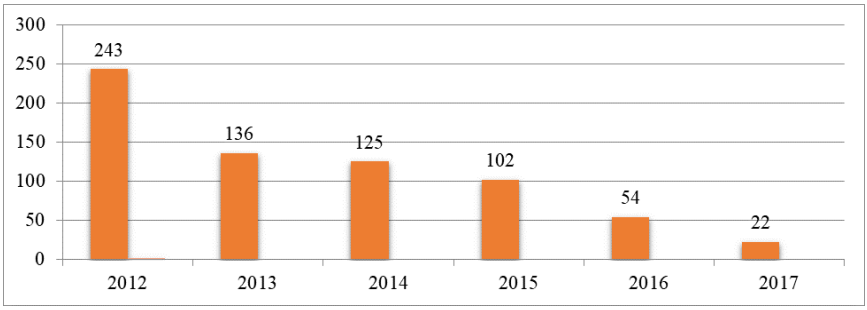

Fig. 1. Distribution of cases of chronic HCV between 2012-2017

Ten (2.5%) patients had co-infection with hepatitis B virus (HBV), and in 14 (2.1%) IL28B polymorphism was determined, of which 2 (14.3%) patients had CC genotype, 11 (78.6%) CT genotype and one patient (7.1%) had TT genotype.

Most of the patients had a mild or moderate liver fibrosis (F1 - 15.8%, F2 - 35.2%, F3 - 23.6%), and 20.7% had advanced fibrosis (F4) (fig. 2).

Of the 408 patients receiving PEG-IFN α and ribavirin, 35% had SVR, but 22.8% had relapses and 36.3% were non-responders (fig. 3).

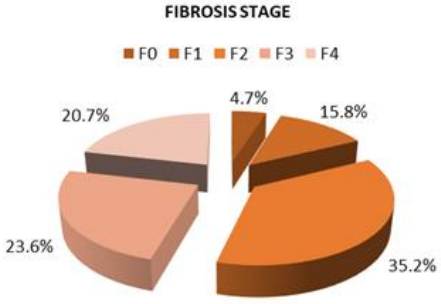

Fig. 2. Group structure according to the fibrosis stage

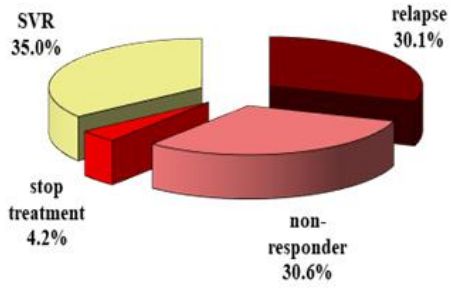

Fig. 3. Distribution of patients according to the post-treatment evolution

More than half of the patients (53%) with hepatic cirrhosis were non-responders, 13.6% had relapses and only 30.3% had an SVR (p = 0.019) (fig. 4).

Of the 408 patients who received treatment, 10 (2.5%) had co-infection with HBV, and 70% of them were non-responders and 20% had relapses (p = 0.05).

Longitudinal evaluation of biological markers

Analyzing the mean level of **HCV RNA** according to the post-treatment evolution, an initially significantly higher mean level was found in the non-responders and those with relapse, compared to the one registered in the patients with SVR (2,345,520 vs 1,632,242 ; p = 0.05) (fig. 5).

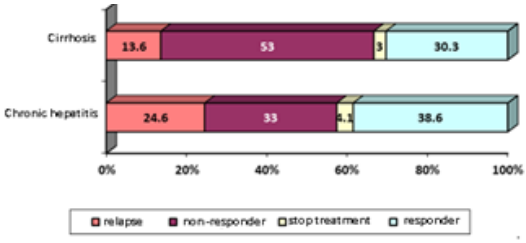

Fig. 3. Distribution of patients according to the diagnosis and evolution

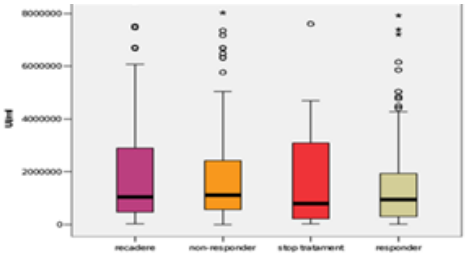

Fig. 5. Mean HCV-RNA values at baseline depending on the post-treatment evolution

At the 12-week evaluation, the mean **leukocytes** values remained in a decreasing trend in all the analyzed groups (p = 0.001) (fig. 6). At week 4, 12 and 24 after the initiation of the treatment, we observed a significant decrease of the mean values of **neutrophils** compared to baseline (fig. 7).

At 4, 12 and 24 weeks after initiation of treatment, mean **hemoglobin** levels decreased significantly compared to baseline (fig. 8). At 24 weeks after treatment initiation, mean **platelet** counts decreased significantly from baseline (p = 0.001), but no significant differences were observed depending on treatment response (p = 0.159) (fig. 9).

Side effects

Of the total 408 patients receiving treatment, 17 (4.16%) discontinued the treatment, most due to severe adverse effects but also to poor adherence to the triple therapy (4 of the patients). Of those with severe adverse effects, 1 patient had pulmonary thromboembolism, 2 patients discontinued treatment due to depression, 8 had severe hematological disorders, 1 patient had hepatic decompensation, and one of them developed autoimmune thyroiditis.

Anemia was noted in 17.9% of patients, statistically significant increase in relapses (39.3%) and patients who did not respond to treatment (18.0% cases) ($p = 0.002$). Leukopenia was found in 26.2% of patients, of whom 34.7% had relapses and 20.1% did not respond to treatment ($p = 0.001$). Only 12.6% of the total study group had neutropenia, of which SVR had 37.2% ($p = 0.012$). Thrombocytopenia was observed in 21.4% of patients, of whom 34.9% had relapses and 20.5% did not respond to treatment ($p = 0.009$).

DISCUSSION

In this retrospective study, carried out between 2012-2017 within the Clinical Hospital of Infectious Diseases "Sf. Parascheva" from Iasi, we noticed a decreasing tendency of the number of patients with chronic HCV infection.

According to the National Institute of Public Health of Romania (CNSCBT), the incidence of chronic HCV infection has a downward trend, from 32 new cases diagnosed in 2012 to only 3 cases reported in 2017 (1, 4, 5, 6, 7, 8).

Of the total patients included in the study, 10 (2.5%) of them had co-infection with HBV. The estimated prevalence of HBV-HCV coinfection is 5-20% in AgHBs positive patients and 2-10% in HCV positive patients, but with a significant geographical variation (2).

We have noticed in our study a higher prevalence of chronic HCV infection in women, with a sex ratio of 1.7 women per 1 man. In an epidemiological study of 2851 adult patients regarding the prevalence of viral hepatitis in Romania, Voiculescu *et al.* demonstrated a significantly higher prevalence among women than in male (9).

Histological examination of the liver is an integral part of the evaluation of patients with chronic hepatitis C. Knowing the stage of hepatic fibrosis is essential for the prognosis and decisions regarding antiviral treatment (10). Recent data have shown

that the development of hepatic fibrosis in hepatitis C is multifactorial and many co-factors have been identified to be involved in increasing the individual risk of developing significant fibrosis or cirrhosis. These include age at the time of infection, male sex, alcohol consumption, obesity, insulin resistance, type 2 diabetes, co-infection with HBV or HIV, immunosuppressive therapy and genetic factors (2).

The combination of PEG-IFN α-2a or α-2b and ribavirin has been the standard of care for the treatment of chronic HCV infection and, in many countries, is still the only therapeutic option available, other than conventional IFN. It is still the standard of therapy in Egypt, a country with an extremely high prevalence of HCV (11).

Until 2011, the only standard treatment regimen for HCV genotype 1 was PEG-IFN and ribavirin for 48 weeks, resulting in SVR rates of 40-50% according to randomized clinical trials (12). SVR rates obtained with PEG-IFN and ribavirin are affected by a number of different variables: HCV genotype (non-1 genotypes are associated with higher RVS rates), serum viremia level before initiation of treatment, degrees of fibrosis and inflammatory activity , as well as the host genotype IL28B (CC genotype is associated with higher SVR) (11).

In our study we observed that the difference between the RVS rate in the patients treated with PEG-IFN α-2a and the patients treated with PEG-IFN α-2b was not statistically significant. PEG-IFN α-2a and PEG-IFN α-2b, the two types of IFN available for the treatment of chronic hepatitis C, differ in their pharmacokinetics and chemical properties (13). In the published articles, there are some observations regarding these two drugs; some argue that PEG-IFN α-2a has a better outcome and many say there are no significant differences (14).

In this study we also set out to identify the biochemical and hematological parameters of the patients receiving PEG-IFN plus ribavirin treatment in order to evaluate the effect of the therapy on the number of leukocytes, neutrophils, thrombocytes and serum hemoglobin level. Various changes were observed during 24 weeks of monitoring, and also these changes were very significant.

Assessing the number of leukocytes during 24 weeks of treatment, a significant decrease is observed in the first 12 weeks in all the studied groups. According to the data published by Iliescu *et al*, the number of leukocytes decreases by approximately 20-30% during treatment (15). Neutrophil values also decreased over the 24 weeks, with a more significant decrease after the first 12 weeks of treatment. Neutropenia is one of the most common reasons for changing the dose of IFN. A granulocyte stimulation factor could be used to stabilize the number of neutrophils during PEG-IFN therapy. However, various studies suggest that IFN-induced neutropenia is not generally associated with an increased risk of bacterial infections (16).

There was also a significant decrease in hemoglobin level after 24 weeks of treatment. Treatment with PEG-IFN and ribavirin is associated with a decrease in hemoglobin concentration and anemia. Anemia is the main adverse effect associated with dose reduction or discontinuation of ribavirin, which can significantly affect SVR, especially in patients with genotype 1. Erythropoietin treatment may increase hemoglobin concentration and allow complete adherence to treatment (16).

In our study, there was a significant decrease in platelet counts, especially at 24

weeks of treatment, but no significant differences were observed depending on the response to treatment (p = 0.159). The effect of IFN on bone marrow results in reduction of granulocytes and platelets during treatment. These are usually moderate if the initial number is normal. However, changes in the dose of IFN are required, especially in patients with a low initial number. This limits the use of IFN in patients with advanced cirrhosis who often have low platelets and are also more vulnerable to infection (16).

In the event of adverse reactions during this therapy, timely dose modification or stopping treatment may be life-saving (17). A study of 257 patients with HCV-induced liver cirrhosis concluded that the adverse effects of PEG-IFN and ribavirin therapy, namely, anemia, neutropenia and thrombocytopenia affect 75%, 19.5% and 65% of patients respectively (18).

CONCLUSIONS

In our retrospective study, we noticed a decrease in the incidence of chronic hepatitis with HCV, probably due to the routine screening of blood products. About a quarter of the patients included in the study had hepatic cirrhosis, most of whom were found in those over 50 years of age, so knowledge of the stage of hepatic fibrosis is essential for prognosis and decisions regarding antiviral treatment. The SVR rate in the studied group was only 35%, this fact demonstrates the need for new antiviral therapies, especially in patients with advanced fibrosis.

NEWS

SGLT-2 INHIBITORS AND CARDIORENAL EFFECTS

Sodium-glucose co-transporter 2 inhibitors (SGLT2i) represents the latest class of hypoglycemic agents used in antidiabetic therapy. These compounds work through a novel mechanism of reducing renal tubular glucose uptake, lowering blood glucose without stimulating insulin release. Since 2008, the Food and Drug Administration has approved the introduction of 4 SGLT2i into therapy, based on studies demonstrating their safety and efficacy: canagliflozin (Invokana®), dapagliflozin (Farxiga®), empagliflozin (Jardiance®) and ertugliflozin (Steglatro®). A fifth SGLT2i, sotagloflozin (Zynquista®) is currently in the latest clinical trials. The cardiovascular outcomes trials have confirmed the cardiovascular and renal clinical benefits of SGLT2i: decreased risk of developing or worsening cardiovascular and renal pathologies in diabetic patients (myocardial infarction, stroke, cardiovascular death or chronic kidney disease). The SGLT2i represents the newest treatment option for type 2 diabetes mellitus with high therapeutic potential (Kluger AY, Tescon KM, Lee AY, *et al.* Class effects of SGLT2 inhibitors on cardiorenal outcomes. *Cardiovasc Diabetol* 2019; 1-13).

ASPECTE CLINICE ŞI EPIDEMIOLOGICE PRIVIND BOLNAVII CU HEPATITE VIRALE ACUTE INTERNAŢI ÎN SECŢIA DE BOLI INFECŢIOASE A SPITALULUI JUDEŢEAN BACĂU, ÎN PERIOADA 1996-2005

CLINICAL AND EPIDEMIOLOGICAL ASPECTS OF PATIENTS WITH ACUTE VIRAL HEPATITIS IN BACĂU COUNTY, FROM 1996 TO 2005 (Abstract): The purpose of the study is to emphasize the clinical and epidemiological peculiarities of acute viral hepatitis in the last decade. **Material and method**: We studied retrospectively the files of 2014 patients, hospitalized with the diagnosis of acute viral hepatitis in the Bacău County Hospital, from 1996 to 2005. **Results**: We saw that the only type the incidence of which lowered in time was the B-type hepatitis. The A acute hepatitis witnessed two epidemic peaks. The clinical cases of the male young patients prevailed. In 91.6% of cases, the infection source could not be established. The average incubation period was 21 days for viral hepatitis A, 65 for B and 80 for C. Hospitalized anicteric forms represented 2.8% of total. Extended forms were recorded with 3.6% patients (50.9% of them with B virus) and severe forms with 10.3% (among these, 66.7% with B virus). A fulminate evolution was noticed with 0.65% of cases. The global mortality was 0.4% and 0.95% for B type. **Conclusions**: We noticed several peculiarities and changes regarding the clinical and epidemiological aspects of acute viral hepatitis in the last decade. **Key words**: ACUTE VIRAL HEPATITIS, VIRAL HEPATITIS B, CLINICAL MANIFESTATIONS, EPIDEMIOLOGY

ACTUAL STATUS OF RADIOTHERAPY IN LOW-GRADE GLIOMA

ACTUAL STATUS OF RADIOTHERAPY IN LOW-GRADE GLIOMA (Abstract): Radiotherapy is commonly used in the treatment of brain tumors but using it for low-grade gliomas is not yet standardized. The purpose of this study is to evaluate the survival benefit of radiotherapy for patients with low-grade gliomas. We also tried to find out how radiotherapy influences the functional status of these patients. **Materials and methods:** We performed a retrospective study on 57 patients admitted in the Neurosurgery department of Bucharest Emergency Hospital in a period of 20 years (between January 1st, 1996 and January 1st, 2016)**.** Obtained data was centralized using *Microsoft Excel* and analyzed with *Stata 13*. **Results:** We found that increasing age ($p = 0.02$) and tumors of astrocytical origin ($p = 0.036$) have a higher risk of relapse, whereas radiotherapy increases time to relapse especially when it is administered without delay ($p = 0.0608$). We also found early radiotherapy to be associated with better functional prognosis ($p = 0.0266$). Increasing Karnofsky Performance Status (KPS) at diagnosis was associated with an increased likelihood of malignant transformation. **Conclusions:** Radiotherapy is proven to significantly increase time to progression for low-grade glioma patients, especially when administered early on. Radiotherapy does not seem to negatively influence the functional status of the patients, but we did not analyze the neurocognitive status of the patients and do not have data regarding short or long-term evolution of this aspect. **Keywords:** LOW-GRADE GLIOMA, RADIOTHERAPY, OUTCOME, SURVIVAL

Low-grade gliomas are defined by the World Health Organization (WHO) as being grade I or II primary brain tumors. They are slow-growing and affect mainly the young adult population in the fourth decade of life. Because patients with these tumors have a long survival rate, a great controversy has risen over the years regarding the best treatment option. Management considered for these tumors range from surgery, radiotherapy, chemotherapy and even "wait and see" approach. Because of the long survival of these patients, one must carefully weigh the impact of treatment on the quality of life of different therapeutic options (1, 2, 3, 4).

OBJECTIVES

In this article we assess the radiotherapeutic option in the treatment of low-grade glioma, aiming to see the impact of radiotherapy on survival of patients, progression of tumor, optimal timing of radiotherapy (early *versus* late) and other variables that

influence survival: tumor site (eloquent versus non-eloquent), histology type (oligodendroglioma / mixed oligo-dominant *versus* astrocytoma), age, estimated tumor volume and Karnofsky performance score (KPS) at diagnosis.

MATERIAL AND METHODS

We performed a retrospective study of 57 patients who were admitted in the Neurosurgical Department of Bucharest Emergency University Hospital between 1996 and 2016. The inclusion criteria were supratentorial and confirmed histopathological diagnosis of low-grade glioma (grade II WHO comprising astrocytoma, mixed oligoastrocytoma, oligodendroglioma), age between 18-70 years old, with no other significant clinical conditions. Mean age was 40 years with a slight male predominance (32 male patients *versus* 25 female patients).

We did not admit in this study patients with prior radiation therapy, chemotherapy or brain surgery for other pathologies. Of the 57 patients, 27 had postoperative radiotherapy either early (18) or delayed (9) by fractioning 54 Gy during a time-period of 6 weeks. Early radiotherapy was defined as intervention as soon as possible after surgery, delayed radiation therapy being deferred until tumor progression was observed. Patients were diagnosed either by biopsy, subtotal resection or gross total resection (as observed by intraoperative inspection and immediate postoperative imaging).

Our primary endpoints were death and tumor progression/recurrence. Secondary endpoints for analysis of functional autonomy, survival after progression and time to malignant transformation were used: Karnofsky performance score (KPS) < 70, death after relapse and malignant transformation, respectively.

The patient database was obtained from the Neurosurgical Department of Bucharest Emergency University Hospital. Patients' records were studied and collected data was analyzed using *Microsoft Excel* and *Stata 13*. We used Kaplan-Meier survival curves and tests of equality (Log rank) for categorical variables (radiotherapy treatment status, tumor site, histology) and the Chi-squared test for continuous variables (age, Karnofsky performance score, tumor volume) to explore whether or not to include the co-variate in the final model. Co-variates who had a *p* value of more than 0.2 after univariate analysis were not included in final Cox models for proportional hazards, except for radiotherapy which we included in our final models no matter the result on univariate analysis. We compared patients who received radiotherapy with those who haven't, but also early radiotherapy with late radiotherapy patients.

RESULTS

We did not find any significant difference when analyzing overall survival by radiotherapy status (p=0,6911). The results for the CPHM based on radiotherapy and KPS were also not significant.

When analyzing overall survival for the radiotherapy group we found that histology type had a significant influence (p=0.0219). Radiotherapy (p=0.0706) and tumor site were added to the final CPHM, but no other significant results were obtained.

On univariate analysis only histology (p=0.0472) proved significant influence on progression-free survival (PFS) for the entire group. The final model including site, age and radiotherapy status showed that the three significantly influence PFS (tab. I).

TABLE I

Progression-free survival predictors analyzed using Cox proportional hazards models. Hazard ratios show us that increasing age and astrocytoma histology have higher risk of relapse while eloquent area and radiotherapy treatment are associated with prolonged PFS.

t	Hazard Ratio	Std. Err.	p > z	[95% Conf. Interval]	
AGE AT DIAGNOSIS	1.043723	.0191919	**0.020**	1.006777	1.082024
SITE	.227095	.1494608	**0.024**	.0625167	.8249337
RADIOTHERAPY	.700632	.3552927	**0.483**	.2593241	1.892941
HISTOLOGY	4.181093	2.855501	**0.036**	1.096369	15.94493

When observing only the radiotherapy group, there was no significant predictor on univariate analysis. Radiotherapy timing (fig. 1), tumor site and KPS were selected for the multiple regression where again no significant result appeared.

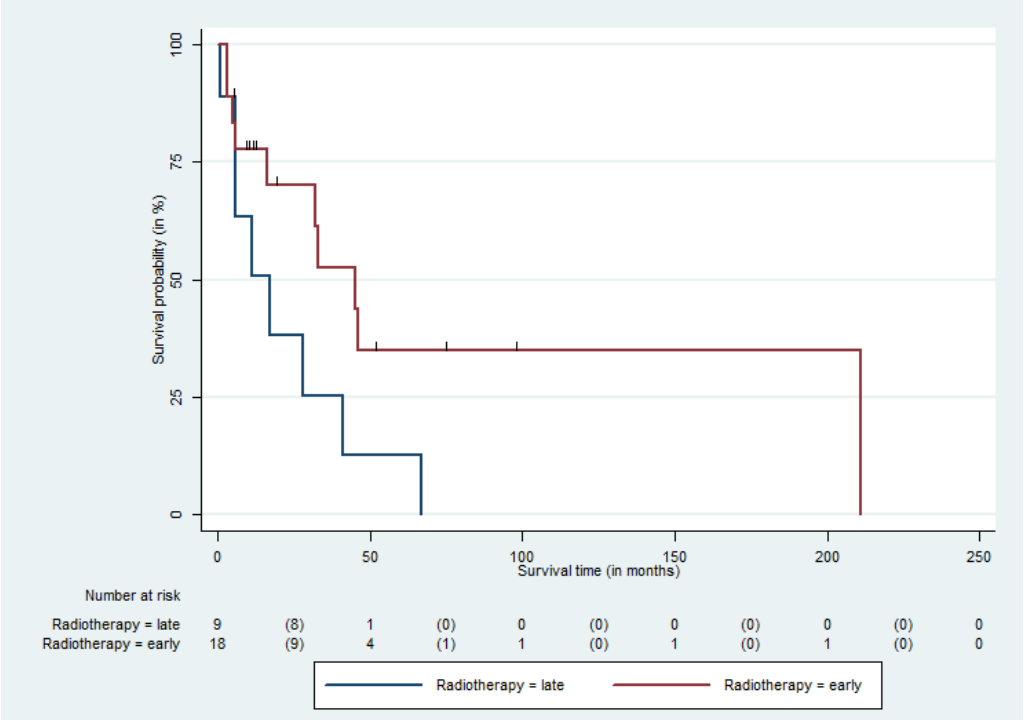

Fig. 1. Kaplan-Meier survival curves showing a longer progression free survival for patients treated with early radiotherapy (in red); numbers marked at the bottom of the table are patients at risk with failed events between parentheses. Vertical axis is the probability of survival; horizontal axis is the survival time in months. Log-rank = 0.0608.

No predictor for functional independent survival was identified when performing univariate analysis or multiple regression for the whole group. In the radiotherapy group, we found early radiotherapy to be significantly associated with greater functional independent survival (fig. 2). Multiple regression based on site and radiotherapy didn't show any significant co-variates.

There were no registered deaths of patients with relapses, so no survival analysis could be performed regarding survival after progression.

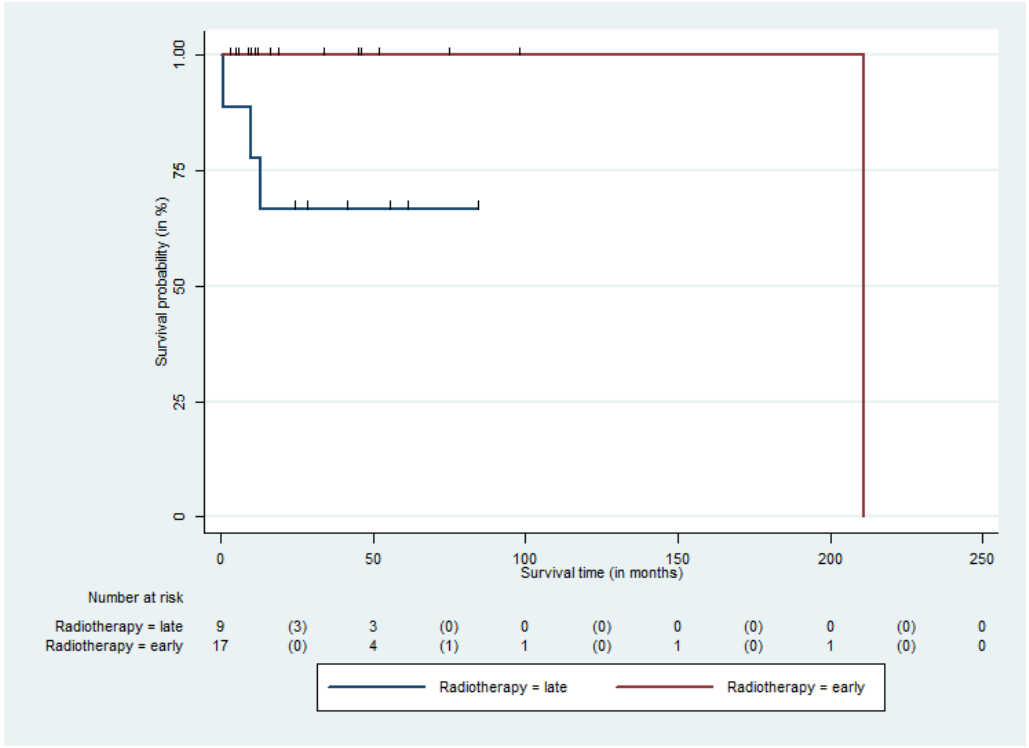

Fig. 2. Kaplan-Meier functional independent survival curves showing better prognosis for early radiotherapy treated patients (in red); numbers marked at the bottom of the table are patients at risk with failed events between parentheses. Vertical axis is the probability of survival; horizontal axis is the survival time in months. Log-rank = 0.0266

Oligodendroglioma / mixed histology was found to suffer malignant transformation less frequently than astrocytoma. KPS was also found to be a predictor for malignant transformation on univariate analysis. For the multiple regression we also added radiotherapy (p = 0.8785) and tumor volume, but only KPS remained a significant co-variate in this setting. When analyzing only the patients who received radiotherapy, timing of the treatment, site of the tumor, histology, age and tumor volume were found non-significant. KPS was the only variable with significance in the univariate analysis. In the final model of multiple regression that included: tumor volume, KPS and radiotherapy status, none of them showed any significance.

DISCUSSION

We could not prove any influence of our studied variables on global overall survival. However, we were able to prove that oligodendroglial subtype has a better prognosis on overall survival analysis in the radiotherapy treatment group.

Tumors of astrocytical origin were 4 times more likely to relapse than tumors of oligodendroglial origin. Older patients were more prone to relapse, along with tumors located in non-eloquent areas. Radiotherapy decreased relapse likelihood with 30%. Eloquent located tumors had a better prognosis which could be explained by the increased likelihood of radiotherapy treatment for this group.

Patients who benefitted of early radiotherapy had a significantly better functional independent prognosis. If radiotherapy increases progression-free survival, we can see why it makes sense that patients treated earlier (when symptomatology is not that important) keep their status for a longer time than those for whom we wait for neurological degradation in order to initiate treatment.

Oligodendroglioma histology was proven to be less aggressive in regard to malignant transformation. Higher KPS at diagnosis was also associated with a higher rate of malignant transformation which may be explained by the fact that patients with a good clinical condition were less likely to be treated aggressively thus more likely to be victims of the natural course of the disease. Also, if the patient lives longer because of a good clinical condition there is more time for the tumor to progress. KPS was important in the radiotherapy treatment group probably because a low KPS urged the physician to initiate treatment as opposed to patients in good condition which are prone to be kept under surveillance.

Although radiotherapy was proven to be effective especially concerning progression-free survival (5, 6), only up to 5% of patients with low-risk low-grade gliomas and up to 30% of patients with high-risk LGG receive this treatment (7). Almost half of the patients in our study were subjected to radiotherapy. Often it is recommended that patients who present with high-risk low-grade gliomas should undergo early radiotherapy treatment, even though this may associate side effects. Usually the decision of initiating early radiotherapy is argued by a few principles: the responsiveness of low-grade glioma to radiotherapy, the diseases' aggressive pathobiological behavior, characterization as a high-risk LGG, the apparent reduction of adverse effects with modern techniques of radiotherapy and possible increased efficacy of commencing radiotherapy at diagnosis (6, 8, 9). In our study we decided not to use classical high-risk/low-risk criteria, like Pignatti risk factors (10). Instead we tried a different approach choosing uncategorized age and a volumetric estimation of the tumor despite other studies not finding volume measurement clinically useful (11). What caught our attention was the fact that radiotherapy determines a decrease in tumor volume over several years (12).

Regarding safety of the treatment for high-risk patients and early complications, recent data shows that tumor progression is responsible for the poorer quality of life of radiotherapy-treated patients and not irradiation itself (13).

Concerning the fact that low-risk LGG patients are less likely to benefit from radiotherapy treatment (7), we do not know for sure if this is a completely justified action

at this time, because after all we are depriving a patient from a verified efficient treatment, that is growing safer and safer with new technologies. If our findings that early radiotherapy is associated with a better functional prognosis are confirmed by other studies, then we have a path for an alternate approach.

Literature data suggests superior brain functions following radiotherapy for diffuse gliomas are stable no matter the timing chosen for treatment administration (14). This fact aids in decision making both for patients and physicians who have doubts about taking this step.

Our study was limited by the small sample size and retrospective design, but nonetheless we managed to get some interesting results not only concerning the behavior of LGG patients, but also the attitude of physicians regarding this pathology.

CONCLUSIONS

Radiotherapy is proven to be effective in the treatment of low-grade glioma, especially regarding progression-free survival with early treatment being further associated with a longer time to progression.

Questions to be answered in the future must direct research towards analyzing clinical status, symptoms control, adverse effects (are they acceptable even for patients where there is no primary intention for radiotherapy) and functional status. An interesting morphological parameter to be investigated is tumor volume and its evolution under the effect of radiotherapy.

NEWS

THE ENDOMETRIOSIS EFFECT ON OVARIAN MALIGNANCY AND ITS IMPLICATION IN GRANULOSA CELL TUMORS

Even if endometriosis is considered a benign pathology, it may play an essential role in ovarian cancer developing. There are data about the endometriosis effect on ovarian cancer, but it is a lack regarding its involvement in granulosa cell tumor. Ashari *et al*. (2019) applied steroid-depleted serum or whole serum from endometriosis patients to the granulosa cells obtained from tubal or infertile women due to a male factor and used flow cytometry and quantitative real-time polymerase chain reaction in order to establish the expression level of inflammatory and apoptotic genes and also the apoptosis level of granulosa cells. The study shown that the granulosa cells which went under treatment with steroid depleted serum from patients with endometriosis presented a considerable increase expression of NFkB/RelA and AKT compared with control group. On the other hand, the genes related to apoptosis had a lower expression in treatment group compared with the control but also the synthesis of saturated fatty acids whereas the levels of unsaturated fatty acids were increased. The implication of steroids on endometriosis is contradictory and the sex hormones and cortisol levels may be modified due to this pathology, leading to alteration of the condition progression. Thus, decreased level of sex hormones in endometriosis females may be considered as a decisive risk factor for granulosa cell tumor (Asghari S, Dizajeykan AV, Ahmadi M *et al*. Evaluation of ovarian cancer risk in granulosa cell treated with steroid-depleted endometriosis serum: role of NF-kB/RelA and AKT. *J Cell Physiol* 2019; 234(7): 12011-12018).

BODY COMPOSITION AND METABOLIC PARAMETERS COMPARISON IN YOUNG WOMEN WITH ANOREXIA NERVOSA AND CONSTITUTIONAL THINNESS

BODY COMPOSITION AND METABOLIC PARAMETERS COMPARISON IN YOUNG WOMEN WITH ANOREXIA NERVOSA AND CONSTITUTIONAL THINNESS (Abstract)**:** Anorexia nervosa and constitutional thinness are two separate medical entities resembling in terms of age and body weight. Even though the former is defined by unique psychological traits, its diagnosis is based solely on clinical judgment, which can sometimes lead to confusion in terms of diagnosis accuracy and clinical management. **Aim:** The aim of this study is to search for discriminative metabolic and body composition traits for each of the aforementioned pathologies. **Material and methods:** In this transversal study we compared two cohorts of female patients aged 11 to 37 years: 11 subjects with on-going anorexia nervosa restrictive type and 12 subjects with constitutional thinness, respectively. The evaluation was comprised of clinical, biochemical and hormonal assessment, as well as of body composition measurements during total body-scan on dual X-ray absorptiometry. **Results:** In anorexia nervosa group versus constitutional thinness, there is a tendency towards lower values of TSH, fT4, IGF1 and insulin (1.6±0.8 *vs.* 2.2±0.8, $p<0.05$, 0.94±0.1 *vs.* 1.07±0.1, $p<0.05$, 105±11 *vs.* 217±59, $p<0.05$ and 3.8±2.2 *vs.* 15.5±1.4, $p<0.05$, respectively), as well as for total fat percentage (22.8±4 *vs.* 26.7±4.6, $p<0.05$). **Conclusions:** Patients with anorexia nervosa differ from subjects with constitutional thinness not only from psychiatric perspective, but also with regard to several metabolic and body composition parameters. **Keywords:** ANOREXIA NERVOSA, CONSTITUTIONAL THINNESS, INSULIN, LIPID PROFILE, BODY COMPOSITION, THYROID, IGF1.

Anorexia nervosa (AN) is a psychiatric condition characterized by food phobia and severe caloric deprivation achieved by extreme starvation and intense physical exercise (1). It predominantly affects young women, being one of the most debilitating psychiatric diseases as it is characterized by multiple somatic injuries due to malnutrition (2), as well as by high mortality rates (3, 4).The current diagnostic criteria as defined by the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) in 2013 consist of low body weight, distorted perception of

body image and fear of gaining weight (1). This new definition of AN is more lenient, because, on the one hand, it leaves to the clinician's appreciation to define "low weight" and, on the other, it no longer imposes amenorrhea as mandatory.

Consequently, due to the more permissive diagnostic criteria, it is sometimes more difficult for untrained clinicians to differentiate AN from a less-known, yet fundamentally different entity, called constitutional thinness (CT). CT patients are in the same age range and have low, but stable body weight, accompanied by normal caloric intake and hormonal, metabolic and reproductive profile (5). They do not exhibit any psychological traits of AN and only resemble it by leanness (6). The condition is considered rare especially in obesogenic societies, but exact prevalence is not known (7). Moreover, there is only scarce evidence in the literature regarding CT state and only a limited number of studies focusing on AN and CT comparison have been published.

The aim of this study is therefore to compare two groups of female patients representative for AN and CT, respectively, in terms of anthropometric, metabolic and body composition parameters in search for significant differences between them in the DSM-5 era.

MATERIAL AND METHODS

The study was conducted between October 2017 and January 2020 in the Department of Endocrinology, Diabetes and Metabolic Diseases of "Elias" Hospital and it originally included 27 female patients 11 to 37 years old, referred to us for malnutrition, anorexia nervosa or thinness management. The cohort was split in two, resulting 15 patients suffering from AN and 12 CT subjects. In the AN cohort, 4 individuals were weight-recovered anorexic patients on ongoing psychiatric medication and were excluded from the analysis for better bias control. All of the remaining subjects had ongoing typical AN restrictive type or have had a lifetime diagnosis of AN restrictive type, without complete remission (they continued to engage in food depriving behavior, were low weight and had attenuated misperception of body image). Six patients from the AN group had secondary amenorrhea at the time of the evaluation. In the CT group, one patient presented with oligomenorrhea and 2 pubertal subjects did not experience menarche by the time of evaluation. Clinical examination assessed that all pubertal girls were Tanner stage 4. All of the remaining patients reported normal menses and no subject was under substitutive hormonal therapy or psychiatric medication. One of the 23 study subjects did not either complete blood tests or body composition due to personal convictions, but anthropometric evaluation is available.

To avoid biased classification of the two medical entities, we performed a careful selection of study subjects and we closely collaborated with pedopsychiatry specialists from the Child and Adolescent Psychiatry Clinic within "Obregia" Hospital, who have large expertise in eating disorders management and gave us guidance during entire study period. As stated above, all of the 11 patients in the AN group expressed intense fear of gaining weight, had misperception of body image and were low weight, and therefore fulfilled the DSM-5 diagnostic criteria. Moreover, eight of them were either already psychiatrically or psychologically evaluated by the time of study visit, or underwent psychiatric evaluation

soon after, which confirmed the above-mentioned diagnosis. To our knowledge, the remaining 3 subjects refused any direct psychiatric or psychologic assessment near the time of our metabolic evaluation. However, there is no doubt on the accuracy of the diagnosis, as they fulfilled the DSM-5 algorithm diagnosis of AN, being on an extremely restrictive diet, remarkably calorie-conscious and very unsatisfied with their body image as they were considering themselves overweight or obese despite their striking leanness. All of the 3 subjects also suffered from secondary amenorrhea. In the group of CT, all 12 subjects stated a frustration in failure to reach a weight that is socially accepted as normal and expressed normal feelings towards food. Also, when asked to rate themselves on a virtual scale from 0 to 10, 0 meaning "extremely lean" and 10 meaning "extremely fat", they evaluated themselves at a maximum 5, as opposed to anorexia nervosa subjects who generally situated above 7.

The study was approved by the Local Ethics Committee of "Elias" Hospital and was conducted in accordance with Helsinki Declaration. Written informed consent was obtained from each patient above 18 years old or from the legal representative for patients under 18, respectively.

Anthropometric evaluation

Physical data such as height, weight, waist and hip circumference were gathered during subjects visit. Height was measured to the nearest 0.1cm and weight was assessed during body composition evaluation on dual X-ray absorptiometry (DXA). Waist and hip circumference were measured in standing position, directly on skin, at the level of umbilicus and greater trochanter, respectively. Body Mass Index (BMI) was calculated as weight/height^2 (kg/m^2). We also assessed the standard deviation of relative weight for child age and sex (BMI-z score)by using external references provided by the Center of Disease Control (CDC) growth charts. For patients 20 years of age or older we used the 20-age BMI-z score reference, in order to have consistent metric of relative weight across study population (8).

Biochemical evaluation

Blood samples were collected in the morning after a minimum eight-hour fasting and were analyzed for plasma glucose, triglycerides (TG), total cholesterol (TC), low-density lipoprotein cholesterol (LDL), high-density lipoprotein cholesterol (HDL), total proteins, urea, creatinine, aspartate aminotransferase (AST), alanine aminotransferase (ALT), insulin, thyroid stimulating hormone (TSH), insulin-like growth hormone 1 (IGF1), free thyroxin (fT4) and 25-hydroxy vitamin D (25 OH vitamin D). The derived-parameter calculated was the Homeostatic model assessment for insulin resistance (HOMA-IR) as fasting plasma glucose (mg/dL) x fasting insulin (μIU/mL)/405(9).

Body composition evaluation

Body composition was assessed during total body scan on DXA evaluation using a GE Healthcare- Lunar iDXA software. Several parameters were included in the statistical evaluation, such as resting metabolic rate (RMR) for non-pediatric population, total fat percentage (TFP) and total fat mass (TFM). We also calculated predicted resting metabolic rate (RMRp) derived from the equation of Harris and Benedict modified by Roza and Shigal (10), RMRp=667.051+ 9.74×(weight)+1.729×(height)−4.737×(age).

Statistical analysis

All data were analyzed using *SPSS version 21.0* and a p value < 0.05 was considered statistically significant. Parametric data were presented as means ± standard deviations (SD) and categorical variables as percentages (%). The Shapiro-Wilk test, visual inspection of the histograms, Q-Q plots and box plots as well as z value calculation for skewness and kurtosis were performed in order to assess the distribution of variables within each group. Group differences in means were compared using a two-sample independent group t-test for normally distributed data and the Mann-Whitney test for non-Gaussian distributions. The Spearman's rank correlation method was calculated to assess the relationship between the variables.

RESULTS

General characteristics

The age range of the 23 subjects included in the study was between 11.3 and 36.7 years, with a mean age of 24.1±7.3 and a median of 25.8. Mean BMI was 16±1.7 kg/m^2 (range 12.24 to 18.27), corresponding to a mean BMI-z score of -2.72±1.3 SD (range -6.23 to -1.39).The cohort was split in two groups depending on the existence of AN diagnosis. Group 1 consisted of 11 AN individuals and group 2 of 12 CT subjects. The six subjects with secondary amenorrhea represented 54.5% from the whole group of AN.

Group comparison

The AN group was characterized by a younger age and a tendency towards smaller abdominal circumference. Both BMI and BMI z-score were significantly lower in AN group. Hip circumference was also slightly lower in patients with AN. Results for anthropometrical parameters are shown in table I.

TABLE I

Anthropometrical characteristics in AN and CT groups

	AN (mean ± SD) n=11	CT (mean ± SD) n=12	Significance value
Age	22.1±7	26±7.5	NS*
BMI (kg/m^2)	15.1±1.7	16.8±1.2	p<0.05
BMI z-score (SD)	-3.4±1.4	-2±0.6	p<0.05
Waist circumference (cm)	60.1±3.7	62.7±2.6	p=0.06
Hip circumference (cm)	86±6.7	88.9±4.3	p<0.05

*NS=non-significant

The biochemical markers considered for statistical analyses (tab. II) showed that the AN group displayed significantly lower values (p<0.05) for fT4, TSH, IGF1, insulin and HOMA-IR, but also a slight increase in total proteins when comparing to CT group. The AN group also had a tendency of increased TG, TC and LDL compared to CT group, but the p value failed to reach the 0.05 threshold. All of the other parameters examined did not reach statistical significance (results not shown).

Regarding body composition analyses, the AN group differed from the CT group in terms of TFP (22.8±4 *vs.* 26.7±4.6, p<0.05, fig. 1) and RMRp values (1090 k±81 *vs.* 1122±46 kcal/day, p<0.05).

In addition, we performed correlation analyses to determine the relationship between glucose homeostasis (assessed by

HOMA-IR) and body composition parameters (TFP, RMR and RMRp) within each group. We found a positive strong association in the AN group between HOMA-IR and TFP (r=0.7, p=0.03). This relationship was not valid for the CT group (r=-0.1, p=0.6). All of the other correlations tested did not reach statistical significance.

TABLE II

Biochemical parameters in AN and CT subjects

	AN (mean ± SD) n=10	CT (mean ± SD) n=12	Significance value
TC (mg/dL)	193.4±43	163±34	p=0.08
LDL (mg/dL)	116.4±36	91.2±27	p=0.07
HDL (mg/dL)	63.6±11.9	61.5±13.6	NS*
TG (mg/dL)	66.9±30	49±11	p=0.08
TSH (μIU/mL)	1.6±0.8	2.2±0.8	p<0.05
fT4 (ng/dL)	0.94±0.1	1.07±0.1	p<0.05
IGF1 (ng/mL)	105±11	217±59	p<0.05
Insulin (μIU/mL)	3.8±2.2	15.5±1.4	p<0.05
HOMA-IR	0.8±0.5	1.17±0.3	p<0.05

*NS=non-significant

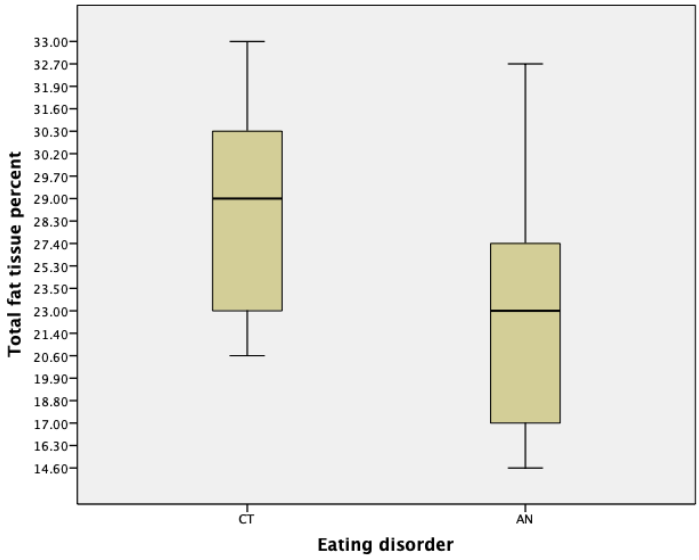

Fig. 1. Total fat percent in CT and AN groups (p<0.05)

DISCUSSION

In this study investigating metabolic parameters and body composition in AN and CT patients, we searched for particularities that can help clinicians better understand the differences between these two rare

entities. The distinction between the two is highly important because it prevents us from unnecessarily stigmatizing lean patients as "anorectic" and also lowers the risk of overlooking AN in a patient without menstrual disturbances(7).

Our study had 3 major findings. First, an impaired lipid profile seems to be representative for AN population, despite their lower weight and total fat percentage.

Probably due to the small number of patients included in the study, our results did not reach statistical significance, but they are interesting to look at, especially because the p value was very close to 0.05 with respect to TC, LDL and TG. This finding highlights a first difference between the metabolic profile of patients with AN versus CT. The increase in cholesterol and TG of AN compared to normal weight subjects has been studied before and, while there is evidence that invalidate this hypothesis (11), most studies plead for hypercholesterolemia and hypertriglyceridemia, as reported in a recent meta-analyses (12). In addition, alterations in the lipid profile seem to be more prevalent for AN restrictive type when compared to any other form of AN or eating disorder (13), or to other causes of malnutrition (14). Moreover, longitudinal studies focused on the dynamics of lipid profile in weight restored AN patients revealed a delay of lipids correction when compared to other metabolic parameters (15). So far, there is no widely accepted explanation for this phenomenon, given that the diet of these patients is typically low in lipids, but some of the hypotheses worth considering are: dehydration, liver dysfunction, increased absorption of exogenous cholesterol due to alterations in gut microbiota, elevated LDL secondary to rapid and severe loss of body fat and to low thyroid hormones or decrease in cholesterol turnover (12, 13, 16).

Second, endocrine disturbances related to metabolic balance were also more pronounced in AN group. This finding is not surprising, as it is widely accepted that AN patients, especially restrictive type, confront themselves with several hormonal misbalances. In relation with our theme, we only focused on thyroid hormones and IGF1 adaptations and found that in AN, contrary to CT, there is a significant drop in IGF1 levels, as well as in TSH and fT4 hormones, pleading for a diagnosis of euthyroid sick syndrome.

There is evidence that in acute forms of AN, free T3 (fT3) levels drop significantly in order to preserve energetic resources, while TSH and fT4 have a slight decrease or remain normal (17). These adaptations are secondary to weight changes and seem to be caused by low levels of leptin that alter the hypothalamic secretion of TRH(18).It is worth mentioning that in 2017, Estour *et al.* proposed fT3 and leptin as metabolic markers for differentiating CT from AN (7).

Similar reasoning explains the drop in IGF1 levels, required in order to minimize expenditure on growth. While AN is a state of malnutrition, low insulin seems to downregulate the hepatic growth hormone (GH) receptor expression (17), leading to acquired GH resistance.GH is a hyperglycemic hormone, and a beneficial effect of high GH-low IGF1 dynamic is preserving euglycemia(19). Both thyroid function and GH-IGF1 axis fully recover after weight restoration (20).

Third, for subjects with AN, there seems to be a strong association between HOMA-IR and TFP. As expected, when comparing these variables separately, insu-

lin, HOMA-IR and TFP were all significantly higher in the CT group, yet the positive correlation between the last two was not valid for lean healthy subjects.

The lower fat mass in AN *versus* normal weight individuals is confirmed by numerous studies (21-24), and, in concordance with our results, there is evidence to be lower than in CT subjects, also (7). Furthermore, we also noticed the RMRp to be lower in AN. This finding is also enforced by existing data (25). Moreover, a group of researchers focused on AN in adolescent girls described positive correlations of RMRp and weight, BMI, fat mass, glycaemia, HOMA-IR, leptin and IGF1 (26). Regarding HOMA-IR results in AN, they suggest a state of insulin sensitivity. This positive association has been demonstrated by earlier researches that consider BMI to be a confounder (27) or describe the association as independent from fat mass (21). Based on these observations, there is a speculation in literature regarding the role of insulin in influencing the reward circuit through its central receptors situated on dopaminergic neurons (27).

In the end, we also want to shed some light on our potentially surprising result on total proteins level, that display higher values in AN group, probably secondary to food supplements administration confessed by some of the AN subjects. This finding has been previously documented by Bossu *et al.* that also described a higher percentage of protein intake in their cohort of AN girls (28).

Study strengths

The present study addresses a less-explored subject and has several strengths. First, we assessed body composition by DXA measurement, which is the gold standard technique and is highly accurate especially in the evaluation of body fat in non-obese premenopausal females(29). Next, we assessed fasting insulin and IGF1 in two categories of patients suffering from neither diabetes nor short stature. Lastly, despite of the lack of an integrative medical center for eating disorders in Romania, we collected data from a group of patients with AN, who are in denial of their condition, being highly reluctant to seek for medical help or to have any scientific exposure.

Study limitations

Overall, we are aware that our study has several limitations. First, the groups were not matched for age and BMI, therefore there are several significant anthropometric differences between them. However, it has the advantage of evaluating representative patients for each category of disease and, in search for a tool for differentiating CT from AN in clinical practice, these differences in BMI and age might come at help. Moreover, in order to increase the homogeneity of the study, we only included female subjects, but both entities, though rare, can also occur in men. Second, several biological parameters with potential relevance to the subject, such as leptin, adiponectin, free T3 or cortisol, were not available. Moreover, we assessed insulin sensitivity by measuring HOMA-IR index, which, opposed to hyper insulinemic-euglycemic clamp, is an indirect, but still efficient indicator of insulin-resistance(30). Another limitation worth mentioning is that, because of its dependency on adiposity and age, there is scarce evidence in the literature regarding accuracy of HOMA-IR index in assessing insulin sensitivity in lean individuals, but available data is rather encouraging (31, 32). Third, due to the poor addressability of AN and CT patients to the doctor, the

study was conducted on a relatively small sample size that may weaken the statistical power of the analyses.

In conclusion, our study postulates that patients suffering from ongoing AN develop several metabolic disturbances that are likely due toa negative energy balance and to an impaired hormonal profile. On the contrary, CT individuals are a unique group of people, who, despite a very low BMI, differ from AN in terms of metabolic, hormonal or body composition parameters.

EPIDEMIOLOGICAL, CLINICAL AND HISTOLOGICAL CONSIDERATIONS REGRADING BASAL CELL CARCINOMA OF THE FACE **(Abstract):** Skin cancer has become one of the most common forms of cancer in recent years. Two major categories of skin cancer have been identified: malignant melanoma (MM) and non-malignant skin cancer (NMSC). Among non-melanoma skin cancer lesions, basal cell carcinoma (BCC) is the most common, with a frequent localization in the face. **Aim:** The current study aims to demonstrate and confirm the frequency of BCC on the face. The increased frequency of these lesions on certain aesthetic units more exposed to the sun proves once again that ultraviolet radiation is the most important risk factor for the appearance of this skin lesion type. **Material and methods:** The study was performed on a group of 95 patients diagnosed with various histological forms of BCC, located in the face. The data has been collected from the observation files, the hospital's reports and eventually processed with the help of the statistical programs *MS Excel 2010* and *SPSS ver. 18.0*. **Results:** The results of the study showed the most frequent affectation of females (86.3%). The elderly are most often affected (average age 71 years old). The anatomical region that BCC develops most often was the nasal pyramid (32.6%). The nodular form of BCC was the most common. **Conclusions:** The increased frequency of BCC on the more preeminent anatomical areas of the face, so more exposed to solar radiation shows once again the importance of avoiding exposure to ultraviolet radiation. Our study confirms the importance of epidemiological studies in detecting risk factors for various pathologies. **Keywords:** SKIN CANCER, BASAL CELL CARCINOMA, MALIGNANT MELANOMA, NON-MALIGNANT SKIN CANCER, FACE.

Basal cell carcinoma (BCC) and cutaneous squamous cell carcinoma (cSCC) represent almost 99% of diagnosed non-melanoma skin cancer, BCC being more frequently reported (1).

BCC is originated from keratinocytes from basal layers of the epidermis, from pluripotent cells of the interfollicular epidermis and from cells localized at the outer root of hair follicles (2). Although BCC has

been described on different sites of the body, face is the most frequently affected skin area, due to direct exposure to ultraviolet (UV) radiation, especially sun (3). It is well known that BCC is locally very aggressive and recurrent, invading adjacent skin and very often, goes profoundly into close structures. Based on clinical and histopathological features different types of BCC have been described, but on the face, superficial and ulcerative types are reported as predominantly (4). Present study analyzed 95 cases of BCCs diagnosed and treated at Plastic Surgery Unit of Iasi, Romania, analyzing correlations with age, gender, anatomical site, clinic-histological type.

MATERIAL AND METHODS

The study lot consisted of 95 participants diagnosed with basal cell carcinoma, admitted in the Plastic Surgery Clinic of the "Sf. Spiridon" County Clinical Emergency Hospital Iasi. All of the patients elected to participate in the study signed the terms and conditions concerning the treatment methods and the processing of data with scientific purpose. The data has been collected from the observation files, the hospital's reports and eventually processed with the help of the statistical programs *MS Excel 2010* and *SPSS ver. 18.0.*

Statistical analysis. The *Skewness, Kurtosis tests* ($-2 < p < 2$) were used, these representing normality tests, available for when the distribution platform for the examination of a variable continues, is in use; the ANOVA test for the analysis of dependent variables inside a study lot and in between lots. The threshold with a significance of 95 percent (confidence interval 95%). I have applied the *t-student test* for quantitative variables, parametrical test that compares the average registered values in two groups with normal distributions and F_{ANOVA} test used in the situation of medium degree comparison for more estimations of the same variable in normal distribution groups.

As nonparametric test, we have used the χ^2 *test* in order to compare two or more same population frequencies distributions. When we compared the ordinary variables from three or more groups, we have used the Kruskall-Wallis correlation. The correlation *quotient* "*Pearson" (r)* represents the (direct / indirect) correlation between two variables belonging to the same group.

RESULTS

Age distribution was homogenous, varying from 31 to 98 years old, median value was 70.67 ± 10.67 years, medium value 71 years old and the result of *Skewness test* p = -1,104. Age wise distribution of cases was homogenous, varying from 31 to 98 years old, the group's value was 70.67 ±10.67 years, average value 71 years and the result *Skewness test* p = -1.104 (tab. I) (fig. 1).

TABLE I

Statistical indicators of age (years)

N		95

Maximum		98
Percentiles	25	67
	50	71
	75	78

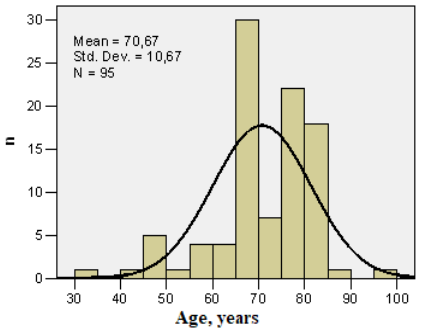

Fig. 1. Distribution of patients by age

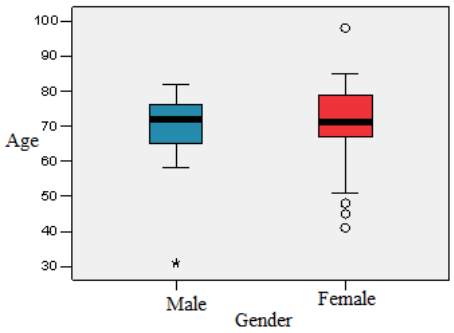

Fig. 2. Average age by sex

Out of all cases 86.3% were female patients, with an average age insignificantly higher in comparison with the cases registered in men (71,01 vs 68,54 years, p=0,440) (fig. 2).

As far as the anatomical region involved, most identified carcinoma cases were localized in the nasal region (32.6%), followed by the facial area (22.1%) and the ocular one (21.1%) (fig. 3, fig. 4) (tab. II).

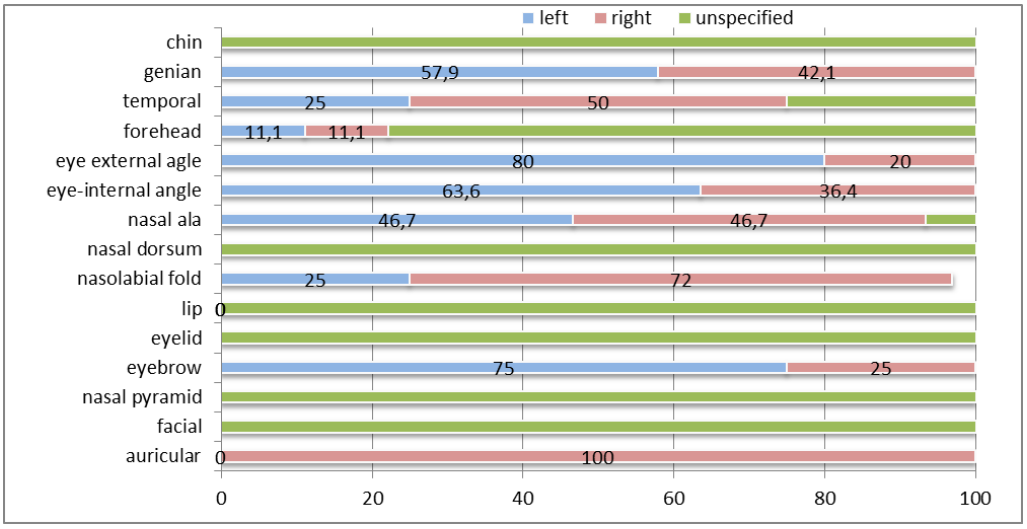

Fig. 3. Distribution by carcinoma location

TABLE II

Distribution by carcinoma location

Anatomical region	Location (%)		
	left	right	Unspecified
Auricular		100	
Facial			100
Nasal pyramid			100
Eyebrow	75	25	

Anatomical region	Location (%)		
	left	right	Unspecified
Eyelid			100
Lip			100

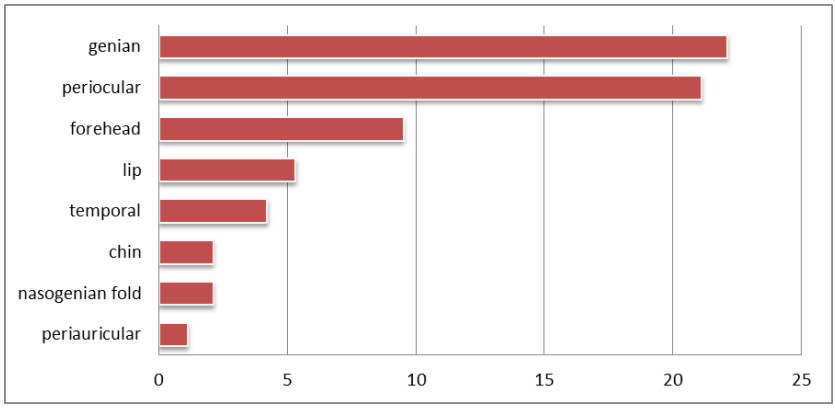

Fig. 4. Distribution by anatomical region

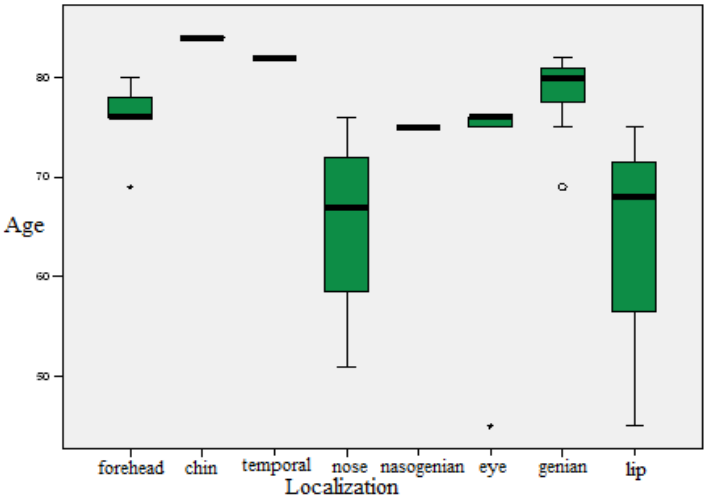

Fig. 5. Average age correlated with the affected anatomical part

Correlation age-anatomical site: younger patients were diagnosed with BCC placed around the lips (62.67±9.06) and older patients presented BCC on the chin (84±0) (p=0.022).

No direct correlation was found between the size of the tumor, regardless the type, and the patient age (r=0.153; p=0.140) (Figure 5). The smallest carcinoma size was associated with the nasolabial region (0.68±0.02), and the largest with the temporal region, the results having intermediate statistical significance (2.26±1.37) (p=0.047) (fig. 7).

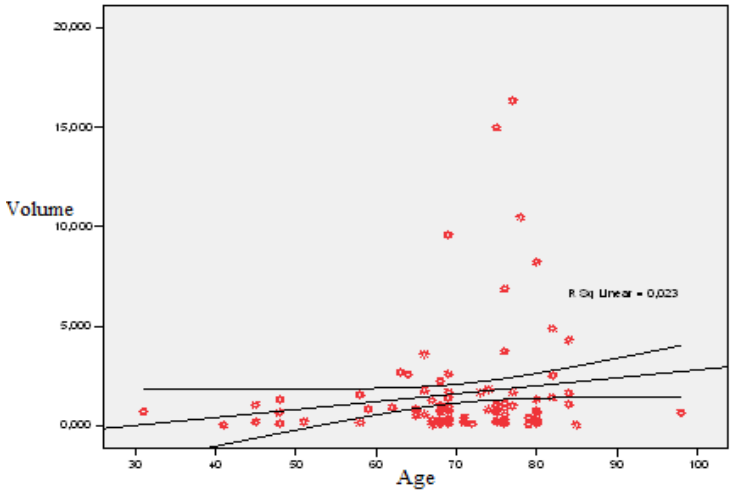

Fig. 6. Correlation of carcinoma size with age

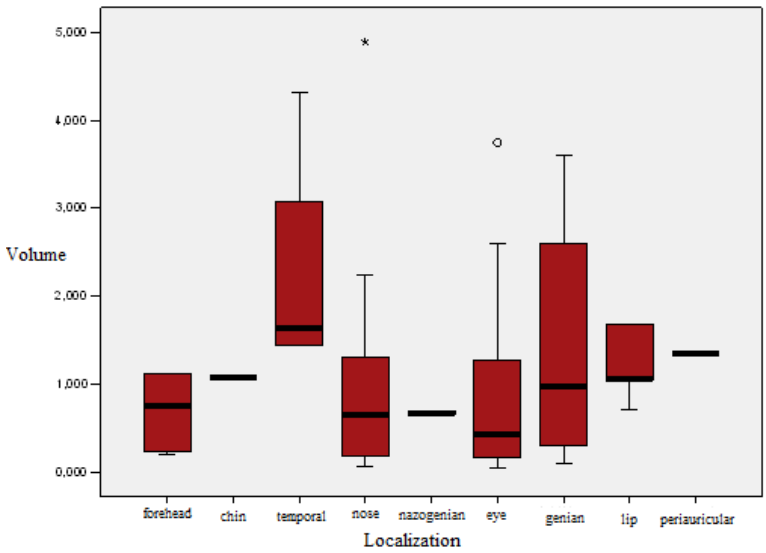

Fig. 7. Average volume depending on the anatomical region

The average size did not register significant differences depending on the anatomo-pathological shape, although the largest volume was associated with the ulcerative form, and the smallest one with the solid form (1.52±0.40) (p=0.929). Among the patients presenting nodular forms, the average size of the carcinoma did not significantly differ between the sexes (fig. 8).

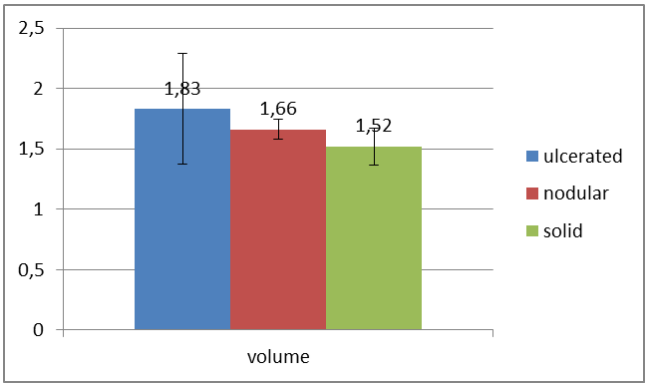

Fig. 8. Average volume depending on the anatomopathological form

In patients with the ulcerated form, the mean size of the carcinoma was significantly higher in females (1.59 ± 0.98 *vs.* 0.41 ± 0.39; p = 0.048), while in the solid form, the mean size of the carcinoma was significantly higher in males (1.58 ± 1.23 *vs.* 0.70 ± 0.43; p = 0.045). In patients with nodular forms, the mean size of the carcinoma did not differ significantly between the sexes (1.00 ± 0.33 *vs.* 1.26 ± 0.48; p = 0.569) (fig. 9).

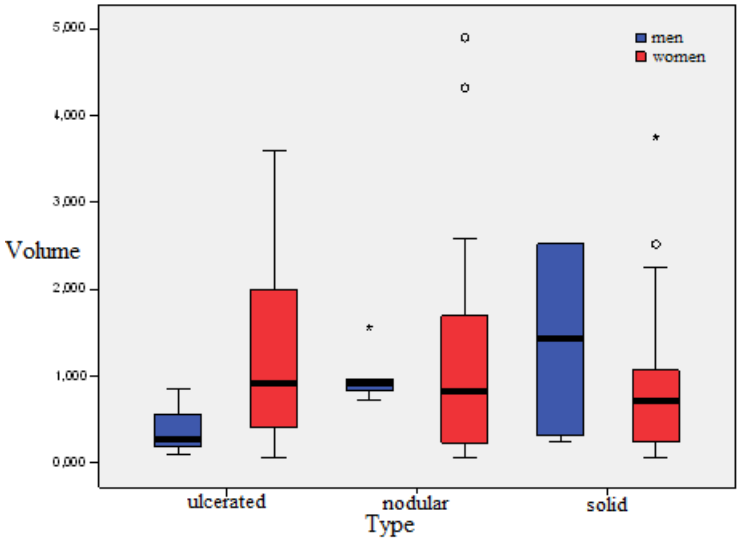

Fig. 9. Average volume by sex depending on the anatomopathological form

DISCUSSION

It is known that BCC frequently occurs on sun-exposed areas, such as the face and neck, but predominantly across the cheeks, nose and periorbital regions (4). Many clinical variants of the BCC (more than 26), have been described, however the most acknowledged classifications tend to presenting superficial, nodular and morphea-like BCC; in daily practice the existence of ulceration is of outmost importance and supports the notion of both ulcerative and non-ulcerative BCC. 81,6% out of BCC had a facial localization (5, 6).

According to more recent studies, BCCs mostly occurred across the nasal area, regardless of the age or gender or the patient. Although BCC was mostly diagnosed among the elderly, younger patients in their thirties, may also develop BCC, especially around the lip area. Women were at higher risk of developing ulcerative BCC in comparison with men, probably due to increased sun exposure, lack of protective measures (men tend to use hats and caps more often than women do), and exposure to artificial light (in tanning salons). No direct correlation between the age of the patient and the size of the tumor was noticed, although the majority of the patients participating in the study were 60-70 years old.

Recent studies by the American Cancer Society show that in 2012, 5.4 million cases of non-melanoma skin cancer (NMSC) were diagnosed. In 8 out of 10 cases, a form of BCC was identified. It is reported that in 40% of patients diagnosed with a form of BCC, a new BCC lesion was diagnosed in the next 5 years of life (5).

The localization of malignant skin lesions on the face, especially in women, will always pose treatment problems, because the aesthetic aspect of the scars is particularly important. Skin lesions, even small, malignant or non-malignant, can cause problems regarding the surgical treatment (7). Although BCC is not an aggressive form of cancer, its ability to cause extensive tissue damage determines that this type of skin lesion to benefit from surgical treatment (8, 9).

When choosing the surgical technique, the surgeon should consider the dimensions of the tumor, the edges of the excision that must be respected, the aesthetic unit of the face at the level of which the tumor formation is found. This will determine the type of anesthesia used. Because facial BCCs are often small, it will not be necessary to use complex surgical techniques (flaps) or other types of therapies (NPWT) (10, 11).

The risk of developing BCC after surgical treatment is reported to be between 5% and 15% (12). The most frequent recurrences were recorded when the initial lesion was located in the lower lip or medial canthus.

Histopathological analysis of excised tumors shows a high frequency of the nodular form of BCC (5, 13). The results obtained by the present study can be compared with those in the literature (14, 15).

CONCLUSIONS

The frequent localization of BCC on the face confirms, once again, that ultraviolet radiation is one of the most important risk factors for such a skin lesion.

Most cases of BCCs were diagnosed in women, during 6-7th decade of life, larger tumor on the forehead, while smallest on perinasal area and a high risk of ulceration

in women, independent of type of BCC or age of the patient. Reducing sun exposure and adequate protection can significantly reduce the risk of BCC on the face.

FATIGABILITY–FROM CONCEPT TO CLINICAL PROFILE. CASE REPORT (Abstract): We present the case of a female patient, aged 57, who undergoes her first cardiovascular evaluation and gets admitted to the emergency room complaining about palpitations, deep physical asthenia, dyspnea on average effort and discrete edema at the lower limbs level. The examination shows a severe anemic syndrome and serositis, with the development, thus, of a systemic immunological affectation at the visceral level. Immunology tests confirmed the diagnosis supposition of systemic lupus erythematosus, the patient meeting 6 of the 11 American College of Rheumatology (ACR) criteria: malar rash, photosensitivity, serositis, hematological affectation, immunological affectation, antinuclear antibodies. The activity of the disease was assessed against the SLEDAI questionnaire (Systemic Lupus Erythematosus Disease Activity Index), which delivered a 12-point scoring, therefore showing a high activity level disease. **Keywords**: FATIGABILITY, SYSTEMIC LUPUS ERYTHEMATOSUS, ANEMIC SYNDROME, SEROSITIS.

Systemic Lupus Erythematosus (SLE) is an autoimmune condition, of complex and incompletely elucidated etiology, characterized by an exaggerated activity of the immune system which triggers the formation of specific autoantibodies (antinuclear antibodies) with the occurrence of inflammation and the destruction of multisystemic tissues (1).

The disease has an increased incidence among female patients (aged 15 to 45, although the onset can be found at any age) suggesting the involvement of hormonal factors in the development of the actual disease; however, men can suffer from more aggressive forms of the disease. Recent studies have shown that there is also an increased rate of disease occurrence in people of color (2, 3).

SLE etiology is unknown, yet it involves a series of genetic, immune, hormonal, and environmental factors, while the main clinical manifestations appear at the cutaneous level (malar rash), muscle–skeletal level (myalgia, arthritis), hematological level (cytopenia) renal level (glo-

merulonephritis)(3).

CASE REPORT

We present the case of a female patient aged 57, from the rural environment, who undergoes her first cardiovascular evaluation, she gets admitted to the emergency room complaining about palpitations, deep physical asthenia, dyspnea in average effort and discrete edema at the lower limbs level.

Upon resuming the anamnesis, the patient appears to suffer from a possible anemic syndrome accidentally diagnosed approximately 5 years ago, in a medical care unit abroad yet without showing any medical documents to support such statement, and without being able to provide any other relevant anamnesis related details.

The clinical examination upon commitment shows malar rash (Fig.1), pale teguments, slightly icteric, discrete myalgia, varices at the level of lower limbs on both sides, dorsal kyphosis with average curve radius, static and dynamic lumbar vertebral syndrome, showing pain upon palpation of the metacarpophalangeal joint I both hands – bilateral level; Blood pressure =100/70 mmHg, ventricular allure=80 beats/minute- heart rate = 80 bpm, rhythmic cardiac murmurs, systolic murmur in the aortic focus 3/6 degree, systolic murmur in the mitral focus – 3/6 degree.

Rest Electrocardiogram shows a sinus rhythm, ventricular rate =59/min, QRS intermediary axis, standard morphology (Fig. 2).

Fig. 1. Malar rash

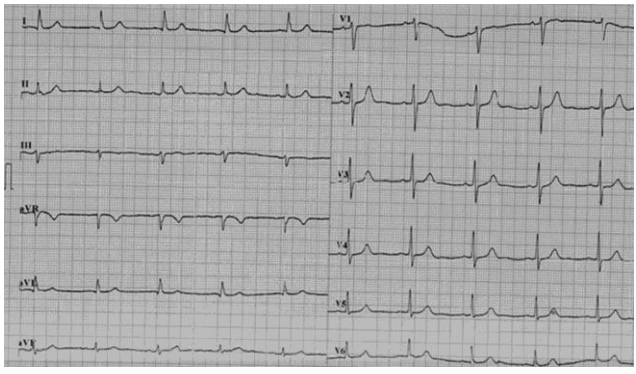

Fig. 2. Electrocardiogram upon commitment

The abdominal ultrasound shows a homogenous liver, lower vena cava = 22 mm, present pericardial fluid; the rest of the abdominal ultrasound test shows no other modifications whatsoever.

At the biological level, we found a microcytic Hypochromic anemia (hemoglobin upon commitment=4,4g/dl), Syderemy =26 µg/dl, Ferritin=10 ng/ml, hyperglycemia, and discreet inflammatory syndrome. The examination of the peripheral blood smear showed an intense erythrocyte anisopoikilocytosis, microcytosis and erythrocyte hypochromia. We have excluded any source of active bleeding at the gastrointestinal tract level or in the gynecological area.

The chest X-ray shows a heart with enlarged transverse diameter, a rectilinear left middle arch, the lung with no pleural –

pulmonary evolutive lesions, calcareous contour aortic knob, moderate intensification of the pulmonary interstitium of the reticular – micronodular display, at the basal level on both sides (fig. 3).

The echocardiographic imaging has showed serositis with a predominant pericardiac determination (the display was that of fluid chronic pericarditis with a thin layer of pericardium fluid displayed at 12 mm circumferential level), with an ejection fraction of 60%. The immunological parameters have endorsed the diagnosis supposition of systemic lupus erythematosus (fig. 4). The patient met 6 of the 11 ACR criteria (malar rash, photosensitivity, serositis, hematological affectation, immunological affectation, ANA – antinuclear antibodies). Moreover, 6 of the Criteria of the Group of Experts in Systemic Lupus International Collaborating Clinics (SLICC) were also met: acute cutaneous lesions, serositis, hematological affectation, increased ANA titer and anti – DNA double – catena antibodies (Ac anti-ADNdc), low C_3 complement level.

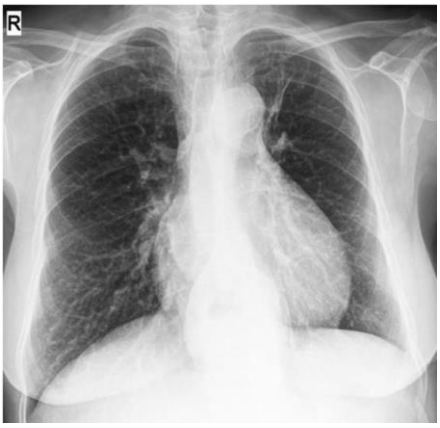

Fig. 3. Chest X-ray

Antinuclear antibodies	338 ↑
Double – catena Anti DNA antibodies	42 ↑
anti SS – A antibodies	475 ↑
anti SS – B antibodies	335 ↑
Cryoglobulins	absent
C3	74 mg/dL
C4	16,4 mg/dL

Fig. 4. Biochemical plasma changes suggestive for SLE

IV with erythrocytes were used, followed by protons pump inhibitors, with a positive clinical evolution, the patient being directed towards the Rheumatology section for registration and therapeutic conduct. The treatment in case of systemic lupus erythematosus aims at diminishing the systemic inflammation with a positive impact, the activity of the disease slowed down leading to a remission of the disease and lowering the occurrence of prophylaxis relapses and therefore the risks of other complications.

DISCUSSION

Fatigability is one of the major symptoms that affects the quality of life, often being described as a *"feeling of physical fatigue and lack of energy deemed to be pathological, excessive, chronic, persistent and problematic"* and it is generally felt when energy reserves are exhausted (4). Moreover, fatigue as common symptom affects more than 90% of the patients suffering from systemic lupus erythematosus (5, 6), with a negative impact on labor performance, family responsibilities and/or

social activity (7, 8) which usually / ultimately triggers a polymorph clinical picture (9).

Cardiovascular pathology varies from subclinical to clinical, with the occasional manifestation of life–threatening complications. The cause of any anemic syndrome should always be identified and specifically treated (10).

Fatigue can be defined as an excessive feeling of exhaustion that does not resolve with sleep or adequate rest (11). More than 50% of patients describe fatigue as their most disabling symptom, furthermore it can cause employment disability and it can have a major impact on the patient's quality of life. Evidence from literature review show an important relationship between fatigue and disease activity which researchers strongly associate with anxiety and depression (12).

Fatigue is a multidimensional concept in rheumatic diseases and is a common symptom in SLE. The treatment and understanding of fatigue remain challenging despite the evolution of alternative therapies (12).

Recent studies have also revealed that cardiovascular disease (CVD) is the main cause of death in patients with SLE. Cardiac diseases in lupus patients may involve the pericardium, myocardium, and endocardium. Compared to the risk in the general population, patients with SLE have a higher risk of stroke, myocardial infarction (MI), congestive heart failure (CHF) and mortality (13). Furthermore, accelerated atherosclerosis is one of the most important comorbidities of SLE and causes of death in relatively young patients (14).

In the course of SLE the most frequent heart manifestation is pericarditis, other causes are rarely observed. It is usually associated with fever and positive antinuclear antibodies (ANA) and treatment should be prompt. In this case, the patient was admitted to the emergency room complaining about palpitations, deep physical asthenia, and dyspnea on average effort, which demonstrates that SLE is characterized by various clinical manifestations.

The complex clinical presentation of SLE often involves multisystemic damage including renal, dermatological, neurological with undulatory, chronic or remission evolution, often with risk of relapses, complications, and comorbidities.

The research of literature shows evidence to support that SLE is an independent risk factor for cardiovascular disease (CVD) development in patients without previous cardiovascular disease. The management, therapies, and cardiac evaluation in patients with SLE are important procedural steps and require a multidisciplinary approach (15).

In the absence of treatment, the prognostic is reserved given the development of systemic complications: cardiovascular, renal, pulmonary, neuropsychiatric, and thromboembolic (16).

Despite current therapeutic advances, the mortality associated with SLE remains high, the probability of survival at 5 years after diagnosis is about 95% and after 20 years is about 78% (17.18).

According to studies, mortality in the first years after diagnosis is associated with active disease and intercurrent infections. Subsequently, the causes of death were reported due to complications of corticosteroid therapy, associated pathologies and last but not least cardiovascular disease.

Lupus nephritis affects about 60% of patients with SLE is one of the most common and severe manifestations of SLE often with poor evolution and prognosis.

In the absence of identification of patients with lupus and lupus nephritis, treatment and rigorous monitoring, the main risk of lupus nephritis is progression to chronic kidney disease (10-30%) (19, 20) with a significant impact on survival, mortality, morbidity and decrease. quality of life (21).

These new data highlight the importance of histopathological diagnosis in lupus nephritis and the usefulness of serial renal biopsy protocols in assessing response to treatment, and the most accurate biomarker in assessing lupus nephritis is renal biopsy (22, 23).

The goal of early treatment is to maintain normal kidney function, prevent skin damage, improve quality of life and longevity among these patients. Current immunosuppressive therapies achieve partial or complete remission in only 50-70% of cases, and complete remission according to the current definition is installed in only 30% of cases (24, 25).

Under immunosuppressive therapy, the diagnostic criteria for remission are under constant debate, especially when its onset should be evaluated, especially due to the fact that many patients achieve remission at least 12-24 months after initiation of immunosuppressive therapy (26).

Current research has also shown that the onset of clinical remission does not necessarily involve immunological remission, just as the lack of clinical response does not necessarily imply persistent lupus nephritis (27, 28).

Relapses due to lupus nephritis cause irreversible lesions and loss of nephrons (29), accelerating the evolution to BCR in the final stage and the need to replace renal function. Periodic nephrological evaluation is essential among these patients.

Currently, approximately 30% of patients diagnosed with lupus nephritis are refractory to current immunosuppression regimens, requiring the identification of new molecules and effective immunosuppressive regimens. According to literature data, although the current evidence is limited, one of the new therapeutic methods being evaluated in severe autoimmune diseases, including SLE, is stem cell transplantation (30, 31).

The occurrence of pericarditis is usually related to the evolution of the disease. According to current guidelines, the appearance of cardiovascular problems in systemic diseases requires a dual treatment: the treatment for the main disease and the treatment of the actual heart disease.

CONCLUSIONS

The report describes the case of a female patient who got admitted into a medical care unit on grounds of the limitation of daily activities as a result of fatigability, further examination showed a severe anemic syndrome and the presence of serositis, with the development of a systemic immunological affectation at the visceral level.

The systemic lupus erythematosus is a complex autoimmune condition, quite often with severe outcomes and a nonlinear evolution, with the risk of relapse in the absence of an accurately established treatment, as well as of complications and comorbidities.

THE RELATIONSHIP BETWEEN NONALCOHOLIC FATTY LIVER DISEASE (NAFLD) AND SELENIUM-DEPENDENT ANTIOXIDANT SYSTEMS

A review conducted by Polyzos S *et al.* (2020) aims to synthesize the existing information on the link between NAFLD, selenium and selenoprotein P, starting from the conflicting literature data link of nonalcoholic fatty liver disease (NAFLD), a disease with no currently approved treatment, with selenium (Se) and selenoprotein P (SELENOP), a glycoprotein synthesized and primarily secreted by the hepatocytes, functioning as a Se transporter from the liver to other tissues. The experimental studies included in the review investigated the association of Selenium with antioxidant defense, which may help modulate hepatic inflammation and fibrosis. Animal studies using Se-deficient diets showed a decrease in glutathione, an increase in lipid peroxidation and a decline in hepatic GPx implying increased oxidative stress and impaired antioxidant function. A number of studies showed a favorable effect when using selenium supplementation. Other studies displayed concern for high exposure to selenium (high doses and/or longer duration) reporting possible adverse effect (formation of nodular regenerative hyperplasia with sinusoidal damage around nodules of the liver). One of the relevant findings is that lower selenium and selenoprotein P levels are found in patients with advanced liver disease. The results of this review pave the way for future research. (Polyzos SA, Kountouras J, Goulas A, Duntas L. Selenium and selenoprotein P in nonalcoholic fatty liver disease. *Hormones* (*Athens*) 2020; 19(1): 61-72).

CLINICAL EVOLUTION OF RARE VARIANTS OF ALPHA-1 ANTITRYPSIN DEFICIENCY IN ROMANIA

CLINICAL EVOLUTION OF RARE VARIANTS OF ALPHA-1 ANTITRYPSIN DEFICIENCY IN ROMANIA (Abstract): Alpha-1 Antitrypsin deficiency (AATD) is a genetic inherited autosomal dominant condition, characterized by decreased serum and pulmonary level of alpha-1 antitrypsin, affecting the lung, liver, rarely skin, associated with an increased risk of emphysema and chronic obstructive pulmonary disease (COPD) early in life, under 40. Under the minimum protection value of Alpha-1 Antitrypsin (AAT) (11 μmol/L or 80 mg /dL), neutrophil elastase may cause the alveolar septa destruction with the early appearance of pulmonary emphysema. Although, AAT is a highly pleomorphic glycoprotein, due by mutations Z and S of approximately 120 alleles. At least 30 AAT alleles other than PI*Z or PI*S were described in literature, some of them as single cases. The prevalence of rare genotypes, other than PI*ZZ or PI*SZ, is between 11% and 21.3%. These rare genotypes were recorded in areas with low prevalence of PI*Z. Rare genotypes of AATD with low plasma levels are Mprocida, Mpalermo, Q0isola di procida, Q0trastevere, Mmalton, Harleen, etc. These evolve clinically with severe emphysema with early onset between 30-40 years. The use in screening programs of gene sequencing for exons 2-5 of SERPINA-1, when genotyping demonstrates the absence of the Z and S alleles, will allow in the coming years to identify several cases of rare variants. Rare variants of alpha1 antitrypsin should be considered on the same risk for emphysema as PI*ZZ. **Keywords**: ALPHA-1 ANTITRYPSIN DEFICIENCY, EMPHYSEMA, RARE VARIANTS.

Alpha-1 Antitrypsin deficiency (AATD) is an autosomal inherited disease, characterized by decreased serum and pulmonary level of alpha-1 antitrypsin (member of the serpin family of protease inhibitors), associated with an increased risk of emphysema and chronic obstructive pulmonary disease (COPD) early in life (1, 2, 3). Alpha-1

Antitrypsin (AAT) is a 52-kDa glycoprotein that functions as the major inhibitor of human neutrophil elastase, a potent serine protease capable of destroying most connective tissue matrices (2, 4, 5). The most common "normal" AAT alleles are M1 (Va1213) (allelic frequency 44-49%), M1 (Ala213) (20-23%), M2 (14-19%), and M3 (10-11%). Individuals inheriting any homozygous or heterozygous combination of these alleles have normal serum AAT levels (20-53 μmol /L or 120-220 mg/dL), enough to provide anti-elastase protection. In normal individuals, the presence of AAT at normal plasma levels keeps the action of neutrophil elastase under control. Under the minimum protection value of AAT (11 μmol/L or 80 mg/dL), neutrophil elastase may cause the alveolar septa destruction with the early appearance of pulmonary emphysema. A reasonable threshold for differentiating normal PI*MM from other genotypes with one or more deficient alleles is 20 μmol/L (100 mg/dL).

Although, AAT is a highly pleomorphic glycoprotein, with approximately 120 alleles being identified, the two major variant mutations, Z and S, represent most cases of the AATD (3, 5, 6). The vast majority of Alpha patients carry the PI*ZZ or PI*SZ genotype, coding for approximately 15% and 25% of cases, respectively, of normal AAT plasma levels (3, 5, 6).

Nevertheless, there are at least 30 AAT alleles other than PI*Z or PI*S associated with absent or reduced levels of AAT. There are limited data about the epidemiology, natural history, clinical manifestations of these rare Genotypes, which are often cited in literature as single cases. The recent study on AAT Deficiency in Romania suggest that rare variants of AAT are more frequent than PI*Z and PI*S in Romania (5).

Lung manifestations and Alpha-1 Antitrypsin Deficiency

Lung manifestations in AATD are emphysema, chronic obstructive pulmonary disease (COPD) and bronchiectasis. Typically, emphysema is pan acinar with basal predominance, and is associated with lower values of alpha-1 antitrypsin < 11 μmol/L; as severe is reduction in plasmatic alpha1antitrypsin value, emphysema develops early and extensively (1, 2). The mean age of emphysema onset in AATD is between 32 and 45 years old, while in typical COPD patients onset of symptoms occur later, after 45 years old.

The early onset of emphysema is related to the level of plasma value, the closer to zero, the earlier is the onset of emphysema. It was observed that individuals with near-zero values of alpha-1 antitrypsin, with the homozygous Null/Null variant, develop emphysema at younger ages than subjects with the AATD homozygous PI*ZZ form (7, 8). The 15 to 20% of the normal plasma concentration of alpha-1 antitrypsin associated with the PI*ZZ allele seems to provide some protection to the lung in comparison with a complete deficiency, like in Null/Null variant (7, 8).

Progression of emphysema in alpha-1 antitrypsin deficiency is known to be at an accelerated rate when compared to common COPD. Frequency of exacerbations appears to be correlated with FEV1 decline and the presence of chronic bronchitis were independent predictors of FEV1 decline (9, 10). Currently, there are uncertainties about patients with severe AATD and rare variants experiencing the highest rate of progression of emphysema, thus reflecting a lack of knowledge of the natural history of this disease (10).

In Italian Registry of AATD, Luisseti

and Ferrarotti found a prevalence of 21.3% cases with rare variants, highest prevalence of rare variants identified overwide, in a country with medium-low prevalence of ZZ (4, 8). Romania seems also to have high prevalence of rare variants and low prevalence of ZZ (5).

Rare mutations and early onset of emphysema

The Italian study demonstrate that COPD and emphysema occur early in life in severe deficiency in rare variants of AATD, like Mmalton, Mprocida, Plowell, Q0procida, I, Mharleen (8). Plasmatic values of alpha-1 antitrypsin in rare variants were severe decreased, compared with ZZ individuals, concluding that severe AAT deficiency in rare variants, especially in smoking exposure, have the same risk and the same natural evolution as ZZ, which is much more studding (2, 3, 4, 8).

Risk factors for early development of emphysema are lower plasmatic values of alpha-1 antitrypsin, smoking exposure, professional exposure to noxes, exacerbations (8, 9, 10). Also, risk factors associated with accelerated decline of lung function in AATD were demonstrated to be smoking exposure, frequent exacerbations > 3/year, chronic bronchitis, extensive emphysema, particularly in the upper zones (11).

Mprocida - rare variant of severe AAT deficiency

Procida allele is an allele based M1 (Val 213) by a T → C mutation at codon 41, exon II; Mprocida is associated with AAT serum levels ≤ 10 mg/dL (n.v. 120-220 mg/dL), codes for an AAT molecule that focuses on immobilized pH gradient isoelectric gels slightly cathodal to the common normal M1 (12, 13). Mprocida it was first detected in the late period of the 80's, in an Italian American family, by Takahashi (12, 13).

The homozygous variant Mprocida/Mprocida evolves with very close to zero plasma levels. The clinical phenotype is not described in the literature as well as the natural history of AATD by Mprocida/Mprocida. Existing data thus far suggest a clinical evolution similar to Null/Null, with an early and severe onset of emphysema < 35 years, rapid decline in pulmonary function in the context of smoking exposure and respiratory noxes (13).

Plowell - rare variant of severe AAT deficiency

Plowell allele (also referred to asQO*Cardiff) is an allele-based is characterized by an A→T transversion at codon 256 exon III, leading to a valine for asparagine substitution (8). This substitution causes a severe AAT deficiency when it occurs in homozygosis form: Plowell/Plowell or in association with other deficiency variants such as PI*Z (14). Plowell evolved with near zero values of alpha1 antitripsina and seems to have an increased risk for early emphysema.

Clinical case-Mprocida/Mprocida

We present the case of a 35-year-old male patient, from Romanian National Registry of AAT Deficiency, with Mprocida/Mprocida, with early onset of severe emphysema at the age of 35 years old and symptoms mimicking asthma. A 35-year-old male, active smoker, with a tabacum consumption of 15 pack/year, construction worker for 10 years, is addressed by the family doctor to the pneumologist for repeated episodes of dyspnea at moderate

efforts with suspicion of asthma. Chest X-ray revealed hyper-inflated lung fields with attenuation of peripheral vasculature, flattened diaphragms, and increased retrosternal clear space. Pulmonary function test revealed moderate obstructive dysfunction (FEV1 = 51%, FVC = 74%); post bronchodilation FEV1 increased with 14% and 300 mL. High-resolution computed tomography showed centrilobular emphysema, predominantly in both lower lobes.

Serum levels of AAT, was determined by nephelometry, using an IMMAGE 800 analyzer (Beckman Coulter, USA); plasmatic value was near zero mg/dL, respectively 0.12 mg/dL. Dried bloodspots (DBS) were used for collecting, transporting blood samples, for analysis and diagnosis, to NITBLD in Warsaw, Poland, the main laboratory in the Central Eastern Europe Alpha-1 Antitrypsin Network. DBS were used for extraction of genomicdezoxyribonucleic acid (DNA) and detecting the presence of Z or S allele, by a real time polymerase chain reaction (RT-PCR), method in the Light Cycler 480 II instrument (Roche Diagnostics Ltd., Switzerland). No Z, no S were found, and we continue with sequence analysis of AAT exons 2-4 was determined by a 16-capillary 3130 x l Genetic Analyzer (Applied Biosystems, USA) (Genomed, Poland) (5). Genetic sequencing determined Mprocida (5). Family testing was following, we diagnosed two daughters with AAT value 91.4 mg/dL, respectively 92.5 mg/dL, which were heterozygous MMprocida. The brother had 0.16 mg/dL AAT plasmatic value, and genetic sequencing detected Mprocida Plowell.

Clinical case- Mprocida/Plowell

The second case we reported was the brother of index case, male, 37 years old, e-cigarettes user for 10 years, but with no professional exposure. Lung function test showed an FVC = 97%, FEV1 = 80%. High-resolution computed tomography showed centrolobular emphysema predominant in inferior lobes. Plasmatic value of alpha-1 antitrypsin was near zero, 0.16 mg/dL, genetic sequencing evidentiate Mprocida Plowell. From our knowledge, there is no case reported with Plowell and Mprocida.

DISCUSSION

AATD is inherited by autosomal co-dominant transmission, characterized by decreased serum and pulmonary level of alpha-1 antitrypsin. Alpha-1 antitrypsin deficiency is still an unrecognized disease, medium years necessary for diagnosis been 9.0 ± 12.1 years (16). Common lung manifestations included emphysema, COPD, bronchiectasis. AAT is a protease inhibitor of the proteolytic enzyme elastase and also of the proteases trypsin, chymotrypsin, and thrombin. The imbalance between neutrophil elastase in the lung (which destroys elastin) and the elastase inhibitor AAT (which protects against proteolytic degradation of elastin), the increasing of elastase secondary to cigarette smoking and infection contribute to local inflammation and tissue destruction in the lung (17). Alpha-1 antitrypsin was encoded by SERPINA-1 gene (MIM +107400) located on the long arm of chromosome 14. At least 120 alleles of AAT (SERPINA-1) have been identified. The normal allele is referred to as "M", AAT is a protease inhibitor, the designation "PI" denotes "protease inhibitor" and the letters denotes the alleles that are present ("PI*MM" refers to homozygosity for the normal gene, while PI*ZZ denotes homozygosity for the Z allele. Some indi-

viduals have compound heterozygosity, meaning that they carry two different mutations of the same gene. Genotyping of the protease inhibitor (PI) using polymerase chain reaction (PCR), can detect the normal M allele and the most commonly known pathogenic variants (e.g., F, I, S, Z).

Variants of AAT can be categorized into four basic groups:

- **Normal** – Normal alleles are associated with normal levels of AAT and normal function.
- **Deficient** – Deficient alleles are associated with plasma AAT levels less than 35 % of the average normal level.
- **Null** – Null alleles lead to no detectable AAT protein in the plasma.
- **Dysfunctional** – Dysfunctional alleles produce a normal quantity of AAT protein, but the protein does not function properly (17).

Data are conflicting regarding the risk of emphysema among PI*MZ heterozygotes so called heterozygous variants (17). For patients who have a low level of AAT, with none I, S, or Z variants on genotyping or phenotyping, sequencing of DNA may be needed to assess for null or other rare deficient alleles.

Regarding the extensive educational efforts and the publication of evidence-based guidelines for diagnosis and management of AATD the recognition of AAT deficiency has be found to be under-recognized, with a 5-8-year delay between the first symptom and diagnosis (18). European Respiratory Society statement described the additional feature that should lead clinicians to test for AATD: Emphysema in a young individual (e.g., age ≤ 45 years).

- Emphysema in a nonsmoker or minimal smoker.
- Emphysema characterized by predominant basilar changes on the chest radiograph.
- A family history of emphysema and/or liver disease.
- Adult-onset asthma (when airflow obstruction fails to normalize after bronchodilators).
- Clinical findings or history of panniculitis.
- Clinical findings or history of unexplained chronic liver disease (18).

The natural history most studied is PI*ZZ, but from natural history of rare variants, a little is known. Rare variants of alpha-1 antitrypsin are published as unique or few cases in literature. A number of rare variants of alpha-1 antitrypsin evaluated with near zero plasmatic values, like Mprocida, have a risk of developing emphysema early in life < 35 years old. Few studies about the evolution of Null variants that demonstrated variants of alpha-1 with near zero plasmatic values of alpha-1 antitrypsin will evolute with severe emphysema and accentuated lung function decline. Risk factors are also important in the evolution of AAT deficiency with rare variants (7). Cigarette smoking, dusty occupational exposure, parenteral history of COPD and personal history of chronic bronchitis, asthma or pneumonia can be important risk factor for lung disease in AATD patients (18). Our examples also demonstrated the role of smoking exposure and construction dusts exposure in the onset of emphysema.

CONCLUSIONS

Rare variants of alpfa-1 antitrypsin could evolve with near zero plasmatic values, and clinically with early onset of emphysema < 35 years old, with a rapid decline in pulmonary function, especially in the context of smoking exposure and res-

piratory noxes and dust. From Romanian screening programme preliminary results, rare variant seems to be more prevalent than PI*ZZ, especially in Nord-West region of the country (5).

The use in screening programs of gene sequencing for exons 2-5 of SERPINA-1, when genotyping demonstrates the absence of the Z and S alleles, will allow in the coming years to identify several cases of rare variants. Rare variants of alpha-1 antitrypsin should be considered on the same

ACKNOWLEDGEMENTS

Many thanks to Aneta Zdral and Joanna Chorostowska from National Institute of Tuberculosis and Lung Diseases from Warsaw, from supporting screening programme in Romania.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest and they received no specific funding regarding this scientific research.

NEWS

THE 4S-AF SCHEME FOR STRUCTURED CHARACTERIZATION OF ATRIAL FIBRILLATION

Atrial fibrillation (AF) is a complex condition requiring holistic management with multiple treatment decisions about optimal thromboprophylaxis, symptom control (and prevention of AF progression), and identification and management of concomitant cardiovascular risk factors and comorbidity. Sometimes the information needed for treatment decisions is incomplete, as available classifications of AF mostly address a single domain of AF (or patient)-related characteristics. The most widely used classification of AF based on AF episode duration and temporal patterns (that is, the classification to first-diagnosed, paroxysmal, persistent/long-standing persistent, and permanent AF) has contributed to a better understanding of AF prevention and treatment but its limitations and the need for a multidimensional AF classification have been recognized as more complex treatment options became available. The authors proposed a paradigm shift from classification toward a structured characterization of AF, addressing specific domains that have treatment and prognostic implications to become a standard in clinical practice, thus aiming to streamline the assessment of AF patients at all health care levels facilitating communication among physicians, treatment decision-making, and optimal risk evaluation and management of AF patients. Specifically, they proposed the 4S-AF structured pathophysiology-based characterization (rather than classification) scheme that includes four AF- and patient-related domains-Stroke risk, Symptoms, Severity of AF burden, and Substrate severity-and provide a hypothetical model for the use of 4S-AF characterization scheme to aid treatment decision making concerning the management of patients with AF in clinical practice (Potpora TS, Lip G, Boriani G, *et al.* The 4S-AF Scheme for Structured Characterization of AF. *Thromb Haemost* 2020; 18(8): 1-9).

THE SURGICAL MANAGEMENT OF LARGE BOWEL OBSTRUCTION IN PATIENTS WITH LEFT COLON AND RECTAL CANCER – A RETROSPECTIVE STUDY

THE SURGICAL MANAGEMENT OF LARGE BOWEL OBSTRUCTION IN PATIENTS WITH LEFT COLON AND RECTAL CANCER - A RETROSPECTIVE STUDY (Abstract): The optimal surgical attitude towards obstructed left colon and upper rectal cancer remains elusive, one of the main postoperative endpoints being to avoid the most dreaded complication of this type of procedures - the anastomotic leakage. **Material and methods:** We conducted a retrospective analysis of all patients with left colon and rectal cancer admitted and having emergency surgery performed in the surgical departments of the University County Hospital of Craiova, Romania, between 2001 and 2018. The timeline analysis showed an increasing interest for single-stage resection and anastomosis in the second decade (2011-2018) compared to the first decade of the study (28% *vs.* 11.2%). **Results:** The incidence of anastomotic leak for these types of procedures remained higher than for the two-stage procedure (15% *vs.* 4.8%), similar to the overall postoperative morbidity (30.3% *vs.* 20%) and mortality (3% *vs.* 1.1%). Postoperative morbidity and anastomotic leak rate were statistically higher in the single stage procedure group when compared with the two-stage procedure ($p < 0.05$). **Conclusions**: Deciding between single-stage resection with anastomosis and a two-stage procedure requires a careful patient selection due to the relatively high risk of anastomotic leak in this specific category of patients. **Keywords:** COLORECTAL SURGERY, ANASTOMOTIC LEAKAGE, COMPLICATION.

Despite the presence of screening programs, colorectal cancer remains the most frequent cause of large bowel obstruction in adult patients (1, 2, 3). An increasing incidence was observed in patients less than 50 years of age with approximately 15%-25% of them presenting with symptoms of obstruction which usually requires emergency surgical procedure. Surgery is however associated with an increased risk of mortality and morbidity, probably because most of these patients have comorbidities, fluids and electrolytes imbalance, and an advanced-stage cancer (4, 5, 6, 7).

Nonetheless, most tumors leading to large bowel obstruction are located on the

sigmoid colon, and around 75% of obstructing malignancies occur distal to the splenic flexure. The optimal management of left-sided large bowel obstruction is less clear and represents a real surgical challenge (2, 8). Treatment of obstructing colorectal cancer, especially in left-sided locations (oLCRC), often involves 2-stage or even 3-stage surgery while primary resection and anastomosis – the so-called one-stage surgery - has been gradually applied in certain patients such as oLCRC to reduce hospitalization due to multiple stage surgery) (9). Due to smaller diameter of the bowel in this location, left colon tumors and rectal tumors will lead more frequently and in a shorter amount of time to bowel obstruction than those localized on the right colon.

MATERIAL AND METHODS

We performed a retrospective study on patients with left colon and rectal cancer which were admitted and underwent emergency surgical treatment in all three surgical wards of the Emergency County Hospital of Craiova, Romania, between 2001 and 2018.

This study was conducted in accordance with the ethical principles stated by the World Medical Association Declaration of Helsinki. Written informed consent was obtained from all subjects involved in the study. The study protocol was revised and approved by the local Ethics Committee of the University of Medicine and Pharmacy of Craiova with code number 56/23.04.2021.

The inclusion criteria were patients admitted in the emergency setting with the diagnosis of bowel obstruction and the site of obstruction either at the level of the rectum or the left colon. The exclusion criteria referred to benign colorectal pathology, prior chemotherapy or radiation therapy for colorectal cancer, and elective surgical procedures.

The aim of the current study was to assess the current management of these patients and compare it with the international literature data. As the possibility of endoscopic stenting was unavailable in our institution, the main option in case of bowel obstruction was open surgery.

Along with descriptive statistics (presented as mean and percentage), a timeline analysis was performed, comparing relevant surgical data such as the type of procedure and the immediate postoperative outcomes, such as postoperative complications, the overall morbidity, and mortality rate. Categorical variables were displayed as absolute and percentage values. Research data were uploaded to the electronic database and the statistical analysis was performed using *Microsoft Excel* (Microsoft, Redmond, USA) and *GraphPad Prism version 8.0* (GraphPad Software, San Diego, USA). For normally distributed values, the t-Student's test was used to assess potential statistically significant differences between the two groups. The statistical significance level was considered for $p < 0.05$.

RESULTS

Between 2011 and 2018, a total number of 442 cases of colorectal cancer were admitted in our surgical department, out of which 157 cases (35.5%) displayed clinical signs of bowel obstruction. Regarding the site of obstruction, most cases (119 cases) had left colon or upper rectum obstruction (group A). Between 2001 and 2010, 377 colorectal cases were admitted in our department, of which 98 patients underwent surgery for oLCRC (group B).

In group A, single step surgery was performed in 33 cases (27.7%), while in 86

cases (72.3%) a two-stage surgery was preferred, with 71% of cases (62 patients) undergoing the anastomosis as a second stage procedure. The operative procedures performed were left hemicolectomy (18 cases), rectosigmoidectomy (10 cases), subtotal colectomy (5 cases), Hartmann procedure (53% -63 cases) followed by anastomosis (45 cases), and loop colostomy (23 cases – 19%). Single stage restoration of digestive continuity after primary resection was performed in 27.7% of patients (33 cases).

In group B, resection with primary anastomosis was performed in 11.2% of cases (11 patients), while Hartmann procedure was performed in 28.5% of cases (28 patients). Only 60% of those patients undergoing Hartmann procedure had a restorative procedure performed (17 cases). Proximal colostomy was performed in 40 patients (40.8%) followed by second stage left or segmental colectomy in 22 patients (tab. I).

TABLE I

Type of emergency procedures performed between 2001-2010 and 2011-2018 for oLCRC

Procedure – stage I	No.	%	Procedure – stage II	No.	%
2001-2010					
Hartmann	28	28.5%	Anastomosis	17	60.7%
Proximal colostomy	40	40.8%	Segmental colectomy	11	55%
			Left colectomy	11	
Cecostomy	7	7.1%	Left colectomy	2	28.5%
Internal diversion	12	12.2%	Left colectomy	7	58.3%
Colectomy	11	11.2%	-	-	-
Total	**98**	**100%**		**48**	**55%**
2011-2018					
Hartmann	63	53%	Anastomosis	45	71%
Proximal colostomy	23	19%	Left colectomy	12	74%
			Rectosigmoidectomy	5	
Colectomy with anastomosis:	33	28%	-	-	-
- left colectomy	18				
- rectosigmoidectomy	10				
- subtotal colectomy	5				
Total	**119**	**100%**		**62**	**72.1 %**

Between 2011 and 2018, the postoperative course was marked by a significantly higher incidence of anastomotic leaks in the single stage restoration group - 15% of cases (5 out of 33 patients), *vs.* 4.8% of cases (3 out of 62 patients) in the two-stage procedure group (tab. II).

Out of the 86 patients in which no anastomosis was initially performed, the global morbidity was 10.4% (9 cases) and 1.1% mortality rate (one case). Most of the patients with postoperative adverse effects had only mild postoperative complications (classified as Clavien-Dindo grade I-II), such as urinary infections (5.8% - 5 cases) and wound infections (9.3% - 8 cases). During the restorative procedure (62 cases), the overall postoperative morbidity was 9.6% (6

cases) with 3 cases (4.8%) of anastomotic leak which were managed by conservative treatment. No postoperative mortality was registered in this group (tab. II).

In the single stage restoration group, the postoperative mortality was 3% (one out of 33 cases), while the postoperative morbidity accounted for 30.3% (10 out of 33 cases). Anastomotic leaks were diagnosed in 5 patients (15%) and in 2 cases (6%) emergency surgery for postoperative peritonitis was required. Death occurred due to severe sepsis in one of these 2 patients.

Postoperative morbidity and anastomotic leak rate were statistically higher in the single stage procedure group when compared with the two stage procedures ($p < 0.05$).

TABLE II

Postoperative outcomes for single-stage *vs.* two-stage procedures in patients with oLCRC operated between 2011 and 2018

	Single stage procedures (33 cases)	Two-stage		p
		Stage I (86 cases)	**Stage II** (62 cases)	
Wound infection	6 (18.1%)	8 (9.3%)	5 (8%)	NS
Anastomotic leak	5 (15%)	-	3 (4.8%)	<0.05
Peritonitis	2 (6%)	-	-	<0.05
Urinary infection	4 (12%)	5 (5.8%)	2 (3.2%)	NS
Sepsis (MODS)	1 (3%)	-	-	NS
Global morbidity	10 (30.3%)	9 (10.4%)	6 (9.6%)	NS
Mortality	1 (3%)	1 (1.1%)	-	<0.05

oLCRC - obstructed left colon and rectal cancer

DISCUSSION

Despite the new additions in the therapeutic armamentarium of colorectal surgery, such as total mesorectal excision, fast-track perioperative management, laparoscopic, robotic and other minimal invasive surgical approaches, many controversies persist concerning the emergency surgical treatment in obstructive cases (10, 11, 12). This problem appears more stringent as the incidence of complicated colorectal cancer remains as high as 40%, with obstructive colorectal cancer accounting for up to a third of the cases admitted for this pathology. To add more complexity to the problem, almost 60% of obstructive cases occur in elderly patients. Given the fact that the location of the tumor in most of these patients (up to 75%) is distal to the splenic flexure, special attention should be paid to the surgical management and the outcome of these specific cases (13, 14).

So far, there is no consensus for the best management of oLCRC, and the quality of evidence for current guidelines is poor (15, 16). In addition to the very survival of the patient, the main issue in the assessment of the optimal treatment protocol for this pathology is the occurrence of anastomotic disruption and leakage, which remains surgeon's most feared complication, and one of the leading causes for postoperative mortality (17). Other aspects to be considered for the optimal management of oLCRC are the quality of the oncologic surgery and of the resected specimen, decrease of definitive colostomies, and on the whole the improvement in the quality of

life (18, 19).

In view of these aspects, the management options for oLCRC diversified during the last 3 decades and were reconsidered, to some extent, in order to include endoscopic procedures such as self-expandable metallic stents placement or to offer a larger role to single stage resection and anastomosis to the expense of two-step procedures. Other measures that contributed to the wider adoption of single stage resection and anastomosis procedures included the optimization of the perioperative diagnostic and therapeutic protocol, with more emphasis on aspects such as complex preoperative clinical assessment, parenteral nutrition, pharmacologic and non-pharmacologic management, and more importantly, improved selection of patients for this type of procedure (20, 21, 22).

In our study, Hartman procedure was preferred for elderly patients, for patients with severe anemia, or for patients with severe comorbidities, in which potential anastomotic leak could have proven fatal. Mortality rate for patients with primary resection and anastomosis was 3%, compared to 1.1% in case of Hartman procedure. Hartman resection remains a good solution for elderly patients, patients with severe anemia, or for those with multiple comorbidities, but primary resection with anastomosis could offer superior results in selected cases, both from a mortality and quality of life point of view (10).

CONCLUSIONS

The optimal therapeutic algorithm of patients presenting in the emergency setting with left colon or rectal obstructive cancer is still difficult, especially in cases where the tumor is resectable, as the choice between single stage resection and anastomosis and two stage procedure requires a careful patient selection due to the risk of anastomotic leak.

WIDE AWAKE LOCAL ANESTHESIA NO TOURNIQUET TECHNIQUE IN HAND SURGERY DURING THE COVID-19 PANDEMIC - PERSONAL EXPERIENCE (Abstract) : Short-time exposure of the patient to the hospital environment and the significantly lower costs make WALANT technique a "gold-standard" anesthesia in hand surgery during the COVID-19 pandemic. **Material and methods**: We studied a group of 180 patients treated for acute and chronic conditions during the first 10 months of the COVID-19 pandemic. A statistical analysis was conducted in order to demonstrate the efficacy and usefulness of the WALANT technique. **Results**: The average length of hospital stay was 118.05 minutes, the mean time of onset of local anesthesia was 12.79 minutes, the average patient waiting time from admission to surgery was 15.72 minutes. We used ANOVA regression, establishing CI 95% and significance F of 95%. A p-value <0.05 was considered statistically significant. **Conclusions**: Using WALANT technique the length of hospital stays and implicitly the risk of contracting SARS-CoV-2 decreases and also the costs are lower, surgical care is good, and patient satisfaction is high. **Keywords**: HAND SURGERY, LOCAL ANESTHESIA, WALANT, COVID-19 PANDEMICS.

The Wide-Awake Local Anesthesia No Tourniquet (WALANT) technique of local anesthesia, initially proposed for small surgeries and wrist surgeries, in time has proven its efficacy and safety, currently being used for extensive surgeries in the field of plastic surgery and orthopedics (1, 2). Obtaining an exsanguinated surgical field by using a solution of a local anesthetic (usually 1% lidocaine) with adrenaline at 1:100,000 without using the tourniquet, which is one of the main causes of intraoperative pain experienced by the patient, is one of the reasons why this anesthesia technique has become very widespread in recent years (3,4). As patient sedation is no longer necessary, there is a better patient and surgeon comfort, the degree of patient satisfaction is high, and the patient's shorter operating time and

length of hospital stay, as well as the substantial decrease in costs have made the WALANT technique to be used for a wide range of surgeries. The myth according to which adrenaline injection would result in ischemia of the anatomical segment at which it is injected has been overcome (5, 6, 7). Given the efficacy and safety of this local anesthesia technique, it is used with confidence and with very good results in hand surgery (8).

From the onset of the COVID-19 pandemic, rules and restrictions were imposed in the epidemiological context, making the admission and surgical treatment of patients with surgical emergencies and especially chronic diseases more difficult (9). A shorter exposure time of the patient to the medical staff and vice versa, the shortest possible duration of hospitalization, reduction of surgical costs without compromising the quality of patient and surgeon comfort, were some of the aspects imposed by the COVID-19 pandemic.

To comply with these rules, a common denominator has been found in hand surgery, namely the use of the WALANT anesthetic technique, with the help of which all these epidemiological criteria can be observed, this being one of the multiple advantages of this local anesthesia technique (10, 11).

The ***study aim*** was to evaluate a group of patients admitted as emergencies or by appointment during the first year of COVID-19 pandemic. Surgical emergencies included in the study were represented by traumas of various etiologies resulting in lesions of the superficial and deep flexor tendons or extensor tendons, with sections of digital collateral nerves, median and ulnar nerves without concomitant vascular damage, foreign body retention, fractures of the metacarpals and phalanges. As to non-emergency surgeries, these were for carpal tunnel syndrome (CTS), Dupuytren's disease (DD), trigger finger (TF), soft tissue tumors of the fingers.

MATERIAL AND METHODS

We studied a group of 180 patients, of which 117 male patients and 63 female patients. Of these, 140 were surgical emergencies, the remaining 40 being chronic conditions. Of the 140 patients with surgical emergencies, 94 patients were male and 46 females. Of the 40 patients with chronic diseases 23 were male and 17 females. The study patients had been admitted to the Clinic of Plastic Surgery and Reconstructive Microsurgery between March 15 and December 15, 2020. The study was approved by the Hospital Ethics Committee and all participants signed a written informed consent.

Of the 180 study patients, 86 were living in urban areas, 62 of them being surgical emergencies and the remaining 24 were patients with chronic condition; of the 94 patients living in rural areas, 78 were surgical emergencies and 16 had chronic diseases. Admission diagnoses for the study patients with chronic conditions were DD - 20 patients, 19 male and one female, CTS - 12 patients, 1 male and 11 female, TF - 3 cases all female, and 5 cases of soft tissue tumors (2 case of glomus tumor of the nail bed and three cases of lipomas of the hand) of which 3 male and 2 female patients. In this group, the right hand was affected in 18 cases and the left hand in 22 cases.

The group of patients presenting to the emergence department had traumas of different etiologies which resulted in wounds with flexor tendons lesions in 15 cases (11 male and 4 female patients), trauma of

finger extensor apparatus or extensors on the back hands in 28 cases (19 men and 9 women), nerve sections (ulnar or median nerves without vascular damage, or digital collateral nerves) in 15 cases (10 male and 5 female).

The surgical indication was established in all cases, consisting of primary tenorrhaphy of superficial and/or deep flexor tendons, extensor tendons, and primary neurorrhaphy in the case of nerve injuries. Of the study group, 54 male patients and 28 female patients had fractures. There were 34 metacarpal fractures (23 male and 11 female patients) and 48 phalangeal fractures (31 male and 17 female patients). All of these patients had indication for open reduction and internal fixation (ORIF) surgery. In this emergency group, the right hand was affected in 63 cases and the left hand in 77 cases. All these patients underwent day-surgery procedures performed under local anesthesia with 1% lidocaine and 1:100,000 adrenaline. 8.4% sodium bicarbonate buffering was not used in any case. In all 180 cases, a 27 G needle was used for the injection, which was inserted perpendicular to the skin into a skin fold kept by the surgeon between the thumb and index finger of his/her non-dominant hand. In all cases the protective equipment was used in accordance with the specific rules recommended during the COVID-19 pandemic and the rules of asepsis and antisepsis.

All patients were notified that they were about to receive the local anesthetic. In none of the cases was ice used to reduce injection site pain. In all cases the anesthetic was injected according to the recommendations: initially 0.2-0.4 mL sub dermally, followed by deep injection. The injection points recommended in the literature for each type of lesion were observed, as well as the recommended amounts to be injected for each anatomical region (e.g. TF cases, no more than 1 mL anesthetic solution was injected into a digital phalange, 15 mL for each digital ray affected by Dupuytren's disease (DD), the amount of anesthetic solution used did not exceed 20 mL for CTS). In patients with chronic conditions requiring surgery for carpal tunnel syndrome (CTS), Dupuytren's disease, soft tissue tumors, or trigger finger the amount of 20 mL was not exceeded. In emergency interventions, the amount of 7 mL/kg was not exceeded.

Intraoperative pain was assessed using the Visual Analogue Scale (VAS) score for pain, bleeding based on the need of using a tourniquet, efficacy of anesthesia depending on the need for intraoperative use of intravenous sedatives, time from admission to initiation of surgery, actual operation time, total length of hospital stays, the number of people the patient had come in contact with during hospital stay, considering the existing epidemiological context.

Statistical analysis

The statistical analysis included demographic, anatomical and surgical variables. The *ANOVA* regression was applied, establishing a 95% CI and significance F of 95%. The *Pearson's* r was calculated, its positive values showing a direct correlation between the two variables, and the negative values exemplifying an inverse, indirect correlation. The further away the coefficient r is from zero, the stronger the correlation, directly or indirectly. A p-value <0.05 was considered statistically significant.

RESULTS

Demographical data. Gender distribution showed a predominance of male patients (64.44%), with an M:F ratio of 1.81.

Legend: M=male, F=female, U=urban, R=rural, RH=Right hand, LH=left hand, P=phalanx, MC=metacarpal, ET=extensor tendon, DD=Dupuytren's disease, FT= flexor tendon, CTS=carpal tunnel syndrome

The distribution by area of residence showed a predominance of urban patients (65.00%), with a U: R ratio of 1.80. We considered other demographic characteristics of the participants as well as anatomical, clinical and diagnosis characteristics, the amount of anesthetic, time from admission to surgery, anesthesia installation time, total time and VAS test scores (tab. I).

The age histogram showed that the most affected age groups were 31-40 years and 41-50 years (fig. 1).

The distribution by type of diagnosis revealed that phalanx fractures were the most common diagnosis (48 cases - 26.67% of total cases), followed by metacarpal fractures (34 cases - 18.89%) (fig. 2).

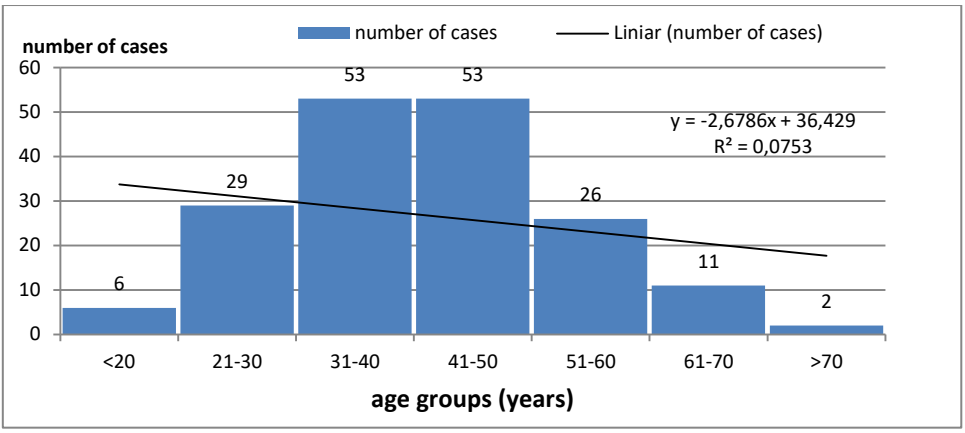

Fig. 1. Age histogram

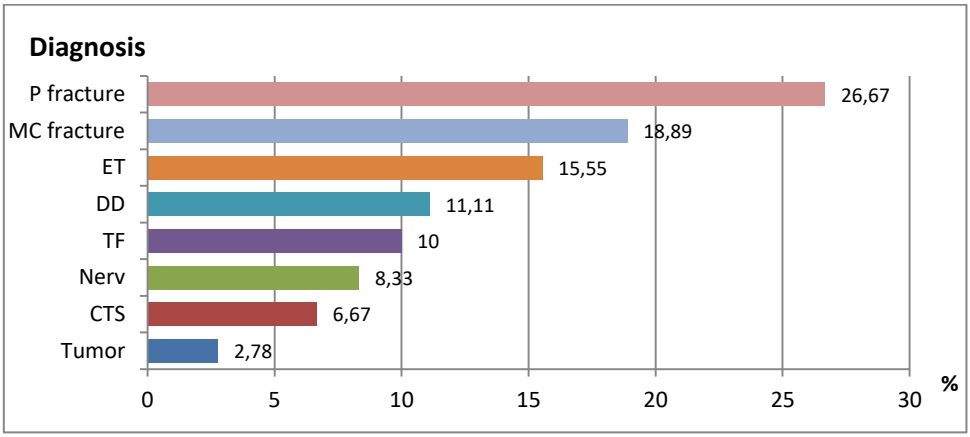

Fig. 2. Distribution of cases by diagnosis

Correlations. Regarding the correlations between different variables, the following results were recorded: the correlation coefficient between patients' age and the amount of anesthetic was r= 0.1121, highlighting a positive, direct, but weak correlation (p= 0.133). The correlation between the amount of anesthetic used and patient's age was statistically positive but weak, meaning that the amount of anesthetic was established based on patients' condition and not their age**.** Correlating patient age with length of hospital stay - surgical start time, a positive correlation coefficient r= 0.1179 was obtained, suggestive of a direct but weak relationship between the two variables (p= 0.114).

The correlation coefficient between patient age and time needed for induction of anesthesia was r= 0.0925, suggesting a positive, direct but weak relationship (p= 0.216). The correlation coefficient between patient age and the amount of anesthetic was r= 0.1121, highlighting a positive, direct but weak relationship (p= 0.465). These two correlations show that the anesthetic solution used in the WALANT technique has maximum efficacy regardless of

patient age when used in the amounts established and indicated in the literature.

The correlation coefficient between patient age VAS test was r= 0.0113, highlighting a positive, direct but weak relationship (p= 0.880). The correlation coefficient between the amount of anesthetic and the results of the VAS test was r= 0.1489, highlighting a positive, direct, weak and statistically significant relationship (p= 0.046).

DISCUSSION

Patient satisfaction was high in all cases, the intensity of pain felt during surgery not being that high as to influence patients' general condition. The VAS test results are not influenced by the amount of anesthetic and patient age, this type of local anesthesia providing full patient comfort during surgery. Regarding intraoperative bleeding, the 4 cases with metacarpal fractures who presented bleeding (2.22%) required the placement of the tourniquet on the arm. These patients had associated cardiac conditions. In none of the study cases was intraoperative administration of intravenous sedatives necessary. No intraoperative accidents or incidents were recorded. There were no cases of ischemia or digital necrosis. From hospital admission, during surgery, until discharge each study patient came in contact with a maximum of 4-5 people, figures modified by the presence or absence of a surgical assistant in the surgical team. If surgery was performed using a different type of anesthesia, a minimum of 2 people forming the anesthesia team (physician anesthesiologist and anesthesiologist assistant) were added to the 4-5 people the patient came in contact with, and the time spent in the operating room would have been extended by a minimum of 30 minutes required to perform loco-regional anesthesia and a longer hospital stay after the surgery for patient monitoring. In these circumstances, the length of hospital stays and the number of contacts during hospital stay and implicitly the risk of contracting SARS-CoV-2 decrease and also the costs are lower, surgical care is of good quality, and patient satisfaction is high.

The advantages and safety of using the WALANT technique have been described and demonstrated over time by multiple studies performed on large groups of patients, WALANT being used for a multitude of pathologies in several surgical specialties (6, 12). The WALANT technique avoids the use of tourniquet, a source of intraoperative pain for the patient, as well as intravenous sedation, associated with the risk of neurological damage, a fact demonstrated by this study in which the use of a tourniquet was required in only 2.2% of cases.

In 2013, Lalonde establishes and demonstrates the safety of the anesthetic solution of 1% lidocaine with 1:100,000 adrenaline, in the amount of 7 mg/kg in hand surgery (13). Lalonde reported in his studies that for optimal visualization in the surgical field, the time needed to achieve the adrenaline vasoconstrictor effect of lidocaine/adrenaline solution is 25 minutes after injection (14). In our study the maximum anesthesia induction time was 15 minutes, with an average of 12.79 minutes. Buffering the anesthetic solution with 8.4% sodium bicarbonate in a 10:1 ratio was not used in any of the cases. The technique of injection and the heating of the anesthetic solution before injection are described in the literature, and in the current study they were performed accordingly (15).

The broad spectrum of hand surgeries in which WALANT can be used as a local

anesthesia technique, as well as its multiple advantages in the context of the COVID-19 pandemic, increase the indications for its use (16).

The short hospital stay and exposure of the patient to the hospital environment, the decrease in the number of people the patient comes in contact with in the operating room, and lower surgical costs tend to make WALANT a gold standard anesthesia in hand surgery during the COVID-19 pandemic and not only (2).The absence of ischemic or necrotic complications in the fingers and hands as a result of using the WALANT technique in the current study are consistent with those described in the literature, thus demonstrating the safety of using adrenaline in the anesthetic solution (17, 18).

The possibility of intraoperative collaboration with the patient allows both the assessment of his/her general condition but specially to perform active intraoperative movement examination of the injured and reconstructed anatomical segment (19). The good locally provided exsanguination obtained by the addition of adrenaline in the anesthetic solution, thus avoiding the use of the tourniquet and the administration of intravenous sedatives is only one of the many advantages of the WALANT technique (20, 21, 22). Both in the literature and in our study, patient satisfaction in terms of intraoperative comfort in relation to the presence of pain, short hospital stays, and lower cost are other benefits associated with WALANT technique (21).

The advantages of this technique represent a way to comply with the hospital protocols and guidelines during the COVID-19 pandemic (9). In our study group the average length of hospital stay was 118.05 minutes. The WALANT technique makes it possible that during the COVID-19 pandemic to treat surgically patients with chronic diseases that should be operated as soon as possible because a delay in surgical treatment may result in worsening disease like soft tissue tumors, finger tumors, carpal tunnel syndrome, or Dupuytren's disease. In the current epidemiological context, these patients would be delayed because of change in the hospitalization rules and decrease of local financial resources (23).

Surgical treatment of metacarpal and phalangeal fractures has good results using WALANT as an anesthetic technique (24, 25). Also, in the current study the outcomes of the surgical treatment of metacarpal and phalangeal fractures were good using the solution of lidocaine 1% with 1:100,000 adrenaline, solution used the vast majority of study cases. The fields in which the WALANT technique can be used have expanded, being frequently used both in hand surgery and in orthopedic surgery (heel) for the surgical treatment of clavicle fracture, distal radius fracture, ankle fracture and other sites (24, 26, 27, 28).

CONCLUSIONS

The WALANT anesthesia technique must be considered by any hand surgeon especially during this pandemic period so that patients to undergo surgical treatment in good conditions, in a short period of time and safely both in terms of surgery outcomes and measures to prevent the spread of coronavirus infection.

CONFLICT OF INTEREST AND FUNDING

NEWS

THE MINDMAP PROJECT: PROCESS AND RESULTS

The MINDMAP (promoting mental well-being and healthy ageing in cities) project implemented a multinational data infrastructure to investigate the direct and interactive effects of urban environments and individual determinants of mental well-being and cognitive function in ageing populations. Using a rigorous process involving multiple teams of experts, longitudinal data from six cohort studies were harmonized to serve MINDMAP objectives. This article documents the retrospective data harmonization process achieved based on the Maelstrom Research approach and provides a descriptive analysis of the harmonized data generated. As methods, a list of core variables (the Data Schema) to be generated across cohorts was first defined, and the potential for cohort-specific data sets to generate the Data Schema variables was assessed. Where relevant, algorithms were developed to process cohort-specific data into Data Schema format, and information to be provided to data users was documented. Procedures and harmonization decisions were thoroughly documented. The MINDMAP Data Schema (v2.0, April 2020) comprised a total of 2841 variables (993 on individual determinants and outcomes, 1848 on environmental exposures) distributed across up to seven data collection events. The harmonized data set included 220 621 participants from six cohorts (10 subpopulations). Harmonisation potential, participant distributions and missing values varied across data sets and variable domains. In conclusion, the MINDMAP project implemented a collaborative and transparent process to generate a rich integrated data set for research in ageing, mental well-being and the urban environment. The harmonized data set supports a range of research activities and will continue to be updated to serve ongoing and future MINDMAP research needs. (Wey TW, Doiron D, Wissa R, *et al.* Overview of retrospective data harmonization in the MINDMAP project: process and results. *J Epidemiol Community Health* 2021; 75: 433-441).

ENDOSCOPIC MANAGEMENT OF POSTERIOR THIRD VENTRICLE LESIONS (Abstract): The pathology of the posterior 3rd ventricle are often complex lesions involving high functional structures and often present in emergency with symptoms caused by the secondary obstructive hydrocephalus. The **aim** of the study was to evaluate the use of ventricular endoscopy in the setting of posterior 3rd ventricle lesions. **Material and methods**: the criteria for inclusion in the study was represented by the patients with posterior 3rd ventricle lesions and hydrocephalus treated endoscopically with ventriculocisternostomy with or without endoscopic biopsy. **Results**: a number of 20 patients were included in the study, most frequent lesions were located at the level of pineal gland 14 cases, followed by quadrigeminal plate 3 case, 19 patients had endoscopic ventriculocisternostomy was effective in 18 patients, one patient needed a redo procedure, and one had an endoscopic cyst fenestration, accurate histological exam was obtained in 13 cases of 14 biopsies. **Conclusions:** Neuroendoscopy is a safe and effective technique for the management of the posterior 3rd ventricle lesions allowing the treatment of associated hydrocephalus and endoscopic tumor sampling during the same surgical procedure. **Keywords**: HYDROCEPHALUS, ENDOSCOPIC THIRD VENTRICULOSTOMY, 3rd VENTRICLE.

Posterior 3rd ventricle lesions often present with hydrocephalus requiring treatment (1) and endoscopic third ventriculostomy (ETV) has been accepted as the procedure of choice for the treatment of obstructive hydrocephalus (2). Endoscopic biopsy of the pineal region lesions is useful in providing tissue for histopathological diagnosis and represent the 1st option in the management of pineal lesions in many centers (3).

Simultaneous ETV and biopsy, using one or the burr holes (4), is nowadays a common strategy for tumors of the posterior 3rd ventricle region (3). Common complications are represented by lesion of the fornix, as the endoscope shaft has to pass the foramen of Monro during the procedure (4) and intraventricular hemorrhage from the biopsy site, which may occlude the stoma from the 3rd ventricle floor (5), sometime requiring an external ventricular derivation (EVD).

MATERIAL AND METHODS

We retrospectively reviewed consecutive patients surgical treated for pineal region lesions admitted to the Department of Neurosurgery, "Professor Dr. N. Oblu" Clinical Emergency Hospital Iasi. Inclusion criteria were as follows: patients with lesions in the pineal region confirmed by MRI at our center between January 2015 and July 2021, enlarged ventricular system based on the preoperative MRI, depictable lesion on the MRI, preoperative MRI evaluation.

The categories consisted of solid and cystic lesions at the level of posterior 3rd ventricle including pineal gland, aqueduct or superior mesencephalon or posterior thalamus.

All patients had undergone preoperative and postoperative neurological and radiological evaluation. Patient data including, age, sex, symptoms, lesion location, surgical procedure, histopathologic diagnostic and outcome were recorded.

Exclusion criteria: patients with no preoperative MRI evaluation, negative MRI for expanding mass, patients in whom no postoperative imagistic evaluation was available.

The outcome following endoscopic procedures was determined by chart review of hospital stay and postoperative clinic and imagistic revisit records at 3 months. Successful endoscopic treatment was defined as decrease of the ventricular system volume and/or decrease of the 3rd ventricle dimension alone requiring no additional treatment for hydrocephalus.

Preoperative evaluation was done based on preoperative MRI images, for the diagnostic of hydrocephalus we used T2 and FLAIR images on axial and coronal plane. Hydrocephalus was defined as enlargement of the ventricular system with an Evans index (6) greater than 0.3, and the presence of the trans ependymal edema, defined as hyperintensity around the frontal horns on T2 and FLAIR sequences. Surgical lesions were evaluated using the T1 sequences before and after contrast injection.

Surgical planning for ETV and biopsy was performed using the T2 sequences in sagittal and coronal plane which allow the setting of entry point, targets (3rd ventricular floor- for ETV/lesion for biopsy) and surgical trajectory.

Surgical procedures were performed using a 30^0 rigid lens endoscope (Karl Starz, Tuttlingen, Germany). After the canulation of right ventricular horn, anatomical landmarks were identified (fornix, septal vein, thalamostriate vein and foramen of Monro), the endoscope is then advanced at the level of the 3rd ventricle and the entry point for ETV is set between the mammillary bodies and infundibulum, on the midline. The stoma is created using a blunt perforator and is enlarged using a 3F Fogarty balloon. When simultaneous ETV and biopsy are planned, the ETV is perform prior to tumor biopsy, this order is advocated since the most pressing clinical condition (that is, noncommunicating hydrocephalus) should be definitively addressed prior to any potential visual obscuration by hemorrhage from tumor biopsy. After successful ETV the endoscope is rotated to obtain posterior view and direction. Once the tumor is identified cupped biopsy forceps are used to sample the tumor, without prior use of cautery in order to reduce artefacts, multiple samples being collected. After biopsy hemostasis is obtain by using saline irrigation, bug bee wire compression or coagulation. After we obtain the hemostasis a final inspection of the stoma and ventricular system is performed. Surgical wound is performed in standard fashion.

RESULTS

This retrospective study includes 20 patients operated at "Professor Dr. N. Oblu" Clinical Emergency Hospital Iasi for symptomatic hydrocephalus caused by lesions located at the level of the posterior 3rd ventricle. Patient age ranged from 8 to 73 years (34.4 mean years) at the time of surgery; there were 8 males and 12 females. All patients presented with symptomatic hydrocephalus, the most common clinical manifestation was represented by headache in 18 patients (90%), Parinaud syndrome in 4 patients (20%), altered level of consciousness in 2 patients (10%) cranial nerve palsy in 4 patients (20%), amblyopia in 2 patients (2%) and one case presented with left hemiparesis (tab. I). The rise intracranial pressure resolved in 19 patients (improved in 1 patient with a cyst of the septum pellucidum in which a unilateral fenestration was performed and resolved after bilateral cyst wall fenestration), patients presenting with Parinaud syndrome and hemiparesis showed no improvement after ETV (tab. I).

TABLE I

Clinical presentation and post-operative course

Clinical presentation	Frequency	%	Resolved	Improved	Unchanged
Headache	18	90	17	1	0
Parinaud syndrome	4	20	0	0	4
Cranial nerve palsy	4	20	1	1	2
Amblyopia	2	10	0	2	0
Altered level of consciousness	2	10	2	0	0
Hemiparesis	1	5	0	0	1

Preoperative MRI identified the primary lesion at the level of the pineal gland in 14 cases (70%), at the level of the quadrigeminal plate in 3 cases (15%), at the level of posterior thalamus 2 cases (10%) and one at the level of the septum pellucidum. There were 2 cystic lesions (pineal and septum pellucidum) with no contrast enhancement and 18 solid lesions, and all showed contrast enhancement except 3 cases (2 located at the level of quadrigeminal plate and one at the level of thalamus).

All patients had endoscopic 3rd ventriculostomy, as primary treatment of hydrocephalus except one (case 20 - in which a cyst fenestration was performed), endoscopic biopsy was performed in 14 cases, in 4 cases was considered unnecessary (cases 8 and 20 - had cystic lesions, and cases 3 (fig. 1) and 11 - had non enhancing quadrigeminal plate lesions) 2 cases (16 and 18) had a profound location within highly functional structures and a stereotactic biopsy was planned, one patient (case 12) had inconclusive biopsy (tab. II).

Histological exam revealed 9 germ cell tumors, 2 pineoblastomas, 1 metastasis and 3 glial tumors (1 grade II astrocytoma and 2 grade III astrocytoma), in one patient the samples were inconclusive.

As complications we had one case of ETV failure (case 7) - the patient presented with a pineal tumor, but intraoperative seeding at the level of the 3rd ventricle floor was identified (fig. 2) ETV and biopsy from both 3rd ventricle floor and pineal

tumor where obtained, and the histopathological diagnosis returned pineoblastoma. After 3 months the patient presented with signs on raised ICP and MRI confirmed the presence of hydrocephalus and progression of the pineal lesion, a redo ETV was performed, intraoperative findings consisted of stoma closure, after ETV the inspection of the prepontine cistern reveled tumoral spreading at the level of the prepontine arachnoid membrane, resection and samplings being undertaken. After 3 days the patient had open surgery with subtotal resection of the lesion.

Another complication was represented by CSF seeding after biopsy of a grade 3 astrocytoma of the quadrigeminal plate (case 4), that developed carcinomatous meningitis after 3 months (fig. 3).

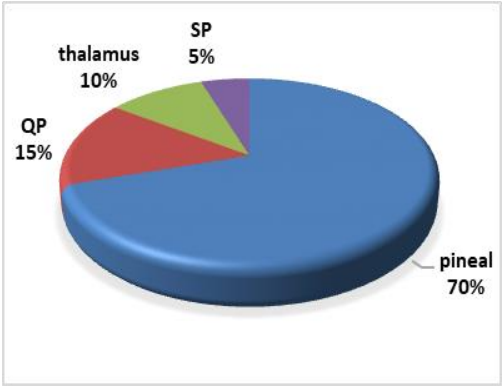

Fig. 1 Lesion location at the level of posterior 3rd ventricle (QP- quadrigeminal plate, SP-septum pellucidum)

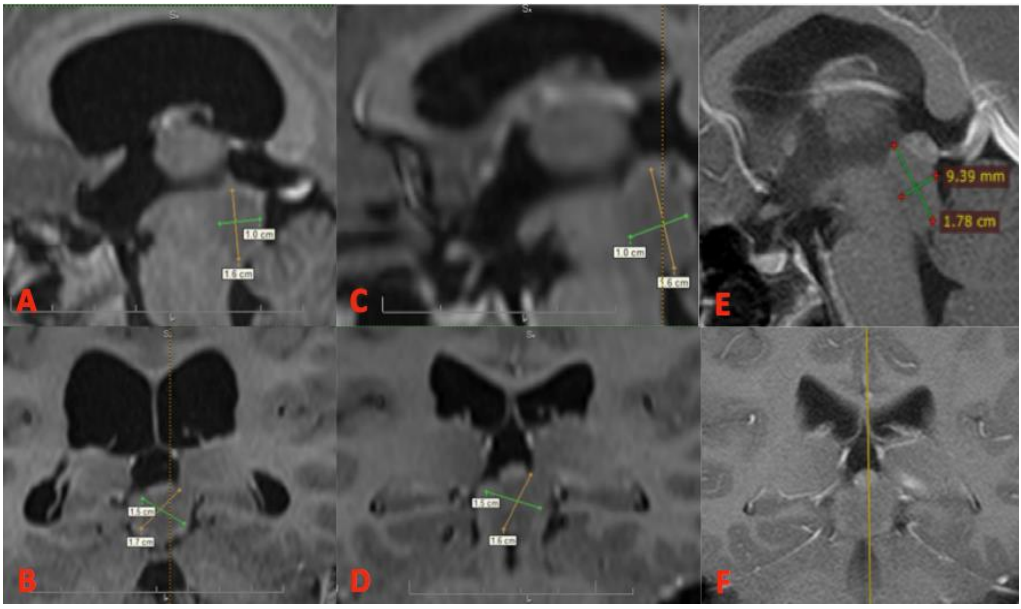

Fig. 2. Quadrigeminal plate glioma treated with ETV and follow-up (case 3)
A and B sagittal and coronal MRI images with contrast showing a non-enhancing lesion of the quadrigeminal plate compressing the aqueduct and causing hydrocephalus, C and D MRI images at 1 year after ETV showing the decrease of the ventricular system and stationary aspect of the posterior lesion, E and F MRI images 3 years after the diagnostic – stable lesion, no hydrocephalus.

TABLE II

Demographics of patients with posterior 3rd ventricle lesions treated endoscopically

Case No.	Age/sex	Location	MRI aspect	Diagnosis	Treatment
1	59,M	Pineal	Solid/enhance	Metastasis	Gamma-knife
2	11,M	Pineal	Solid/enhance	Teratoma	Surgery
3	8,F	Q plate	Solid/no enhance	Indolent glioma	Follow-up
4	55,F	Q plate	Solid/enhance	Anaplastic astrocyto-ma	CHT+ RxT
5	74,M	Pineal	Solid/enhance	Germinoma	CHT+ RxT
6	67,F	Pineal	Solid/enhance	Germinoma	CHT+ RxT
7	31,F	Pineal	Solid/enhance	Pineoblastoma	Surgery + CHT+ RxT + Redo ETV
8	57,M	Pineal	Cyst/no enhance	Pineal cyst	Follow-up

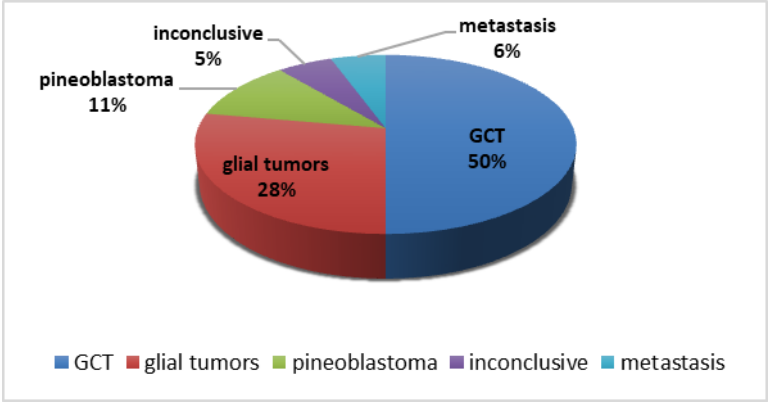

Fig. 3. Lesion distribution according to histologic examination (GCT-germ cell tumor, * results from stereotactic biopsies were included)

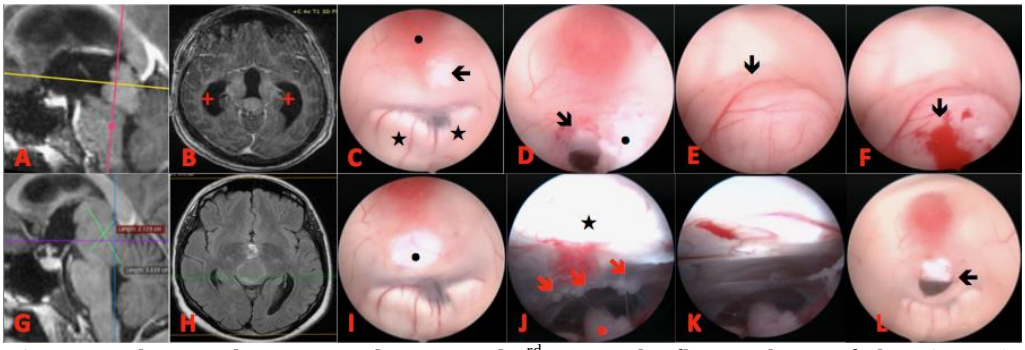

Fig. 4. Synchronous lesions pineal region and 3rd ventricular floor with ETV failure (case 7). A and B contrast enhanced MRI sagittal and axial images showing enhancing pineal tumor with hydrocephalus (+), C intraoperative findings from the level of the 3rd ventricle floor with identification of the infundibular recess (point), mamillary bodies (stars) and synchronous lesion at the level of 3rd ventricular floor (arrow), D intraoperative image showing the created stoma (arrow) and biopsied lesion (point), E and F intraoperative images showing the tumor (arrow) from the posterior 3rd ventricle before and after biopsy, G and H MRI images showing the progression of the posterior lesion and hydrocephalus, I intraoperative image from 2nd surgery showing the closure of the stoma (point), J exploration of the prepontine cistern after 2nd ETV with identification of dorsum sellae (star), basilar artery (point), and dissemination at the level of the arachnoid membrane (stars), K image after resection of the infiltrated arachnoid, L aspect of the newly created stoma (arrow).

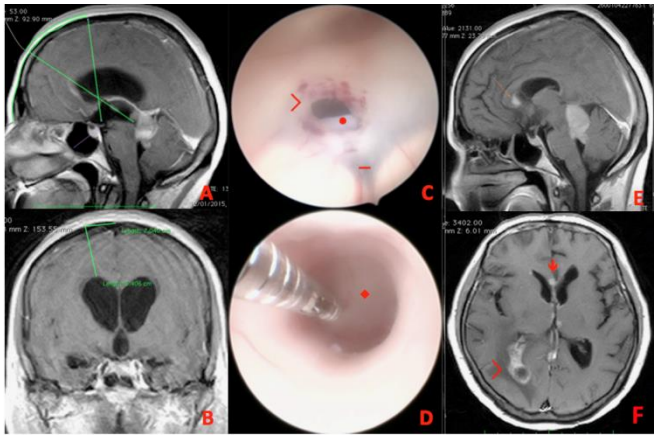

Fig. 5. CSF seeding after endoscopic biopsy (case 4). A and B contrast enhanced preoperative MRI images (sagittal and coronal) showing contrast enhancing lesion at the level of the quadrigeminal plate and aqueduct and hydrocephalus and preoperative planning (green lines) - planned trajectories using 2 burr hole technique. C and D intraoperative images C newly created stoma on the 3rd ventricle floor (arrowhead), basilary artery (point) and mamillary bodies (line), D biopsy of the tumor (diamond) E and F postoperative MRI images at 3 months showing CSF dissemination at the level of the genu of the corpus callosum (arrow) and at the level of the right occipital horn of the lateral ventricle and a slight progression of the primary tumor.

From the patients with germ cell tumors those harboring germinomas were treated successfully with chemotherapy and radiation therapy except the patient with pineal teratoma (case 2) that suffered a rapid degradation and needed emergency surgery for tumoral resection, the patients with anaplastic astrocytoma had radiation therapy and Temozolomide and the patient metastasis was sent to gamma-knife radiotherapy while the patients with pineoblastoma (cases 7 and 19) had surgical resection and adjuvant radiotherapy.

DISCUSSION

The posterior 3rd ventricle comprises the pineal region with the pineal gland inside the quadrigeminal cistern and surrounded by several important structures i.e. third ventricle, tectum, the complex of the great cerebral vein of Galen, thalamus and splenium of corpus callosum (7) thus being one of the most difficult and challenging regions for surgery in terms of surgical approach and neurological outcome.

Tumors of the posterior 3rd ventricle are mainly represented by pineal parenchymal tumors, germinal tumors, gliomas and miscellaneous tumors (meningiomas, metastases, ependymomas, dermoid and epidermoid tumors, pineal cyst) (8, 9). Most of the tumors in the pineal region are germ cell tumors, divided in germinomas and non-germinomatous germ cell tumors (choriocarcinoma, embryonal carcinomas and teratomas) (10). In our series we had a heterogeneous mix of the histopathologic spectrum, but most frequent lesion were germ cell tumors (50%) followed by glial tumors 28% and pineoblastomas 11%, which are in accordance with the data from the literature for germinal tumors and pineoblastoma (11-13). In previously published series gliomas account for 10% (12) but in our study they represent 28% of the cases, probably due to the inclusion of cases located at the level of the posterior thalamus.

The main feature of posterior 3rd ventricle lesions is the fact that cause hydrocephalus, which determine symptoms and require treatment.

90% of patients in our series presented with signs and symptoms of rides ICP along with secondary amblyopy and/or VI nerve palsy leading to visual deterioration.

Clinical status is completed by Parinaud syndrome (20%) due to superior collicular compression, resulting in up-gaze palsy, near-light reflex dissociation, pupillary asymmetry and nystagmus (14), and hemiparesis (1 case) due to cerebral peduncle involvement or by compression of the posterior limb of the internal capsule.

Other clinical manifestations that are cited in the literature such as cerebellar ataxia due to compression of the superior cerebellar peduncle/vermis, endocrine dysfunction due to invasion of the 3rd ventricle floor were not observed in our series (14). There are data in the literature sustaining the synchronous presence of germinomas, both at the level of posterior 3rd ventricle and suprasellar region, some centers considering this situation as pathognomonic for germinomas and considering the biopsy unnecessary (15). In our series we had a patient with synchronous lesions (case7-figure 3) where the histopathologic exam returned pineoblastoma, thus confirming that no imagistic or intraoperative finding could elude the histological examination, but the particularity of the case is that the lesion was identified intraoperative and was not visible on preoperative MRI.

The management of posterior 3rd ventricle lesions is based on two pillars, the

treatment of hydrocephalus and the treatment of the primary lesion depending on the histopathological type(16), which vary from follow-up, chemotherapy, radiation therapy and surgery, alone or in various combinations. In order to have histopathologic diagnosis tissue samples should be obtained, either by stereotactic guidance or by endoscopic biopsy.

Stereotactic biopsy pose some challenges given the proximity of important neural and vascular structures such as internal cerebral veins, straight sinus and does not address the hydrocephalus, and it has a high rate of complications, mostly postoperative bleeding (17). On the other hand, the endoscopic approach is capable in resolving the most urgent problem, the hydrocephalus, which is often life threatening and gives the possibility to obtain tissue samples for pathological exam in the same surgery. There is still debate in the literature weather to use a single burr hole for both procedures or two separate burr holes with two different trajectories (3, 4), although it is recommend the use of single burr approach for lesions that pass anteriorly the interthalamic adhesion (3). In our series we used single burr hole in 93% of the cases and two burr holes in 1 case in which we used a 0° endoscope, of mention the single burr technique cannot be performed using the 0° degree endoscope without damaging the brain. By accurate image study and the use of 30° degree scopes and slightly flexible instruments, we were able to calculate the optimal trajectory in order to perform ETV and sample lesions that are posterior to interthalamic adhesion without damaging the fornix.

In the setting of this approach the sequence of surgical procedures is to do first the ETV in order to resolve the hydrocephalus (18), the most urgent problem, and then to perform the biopsy which usually produce some bleeding thus compromising the realization of ETV. It is known that in ventricular endoscopy a quantity of 5ml of blood in the ventricular system is enough to obscure the scope vision (2).

Sometimes endoscopic biopsy is not suitable, if the tumor has no exophytic component and is surrounded by a layer of functional neural tissue such as mesencephalon, quadrigeminal plate or thalamus.

Reports from the literature are reveal a success rate of histological diagnosis trough endoscopic biopsy ranges from 88% to 95% (1, 19), we had a success rate of obtaining histological diagnosis after endoscopic biopsy 93% of the cases, more precisely we had one case (case 12) in which the samples were very small and thus not sufficient for diagnosis. Stereotactic biopsy on the other hand has a comparable success of diagnosis (94%) but a higher rate of complication with reported morbidity rate as high as 8.1% (20).

Germ cell tumors have a good response to chemotherapy and radiation therapy, surgery seldom being necessary(16), hence the importance of obtaining bioptic material for diagnosis and thus avoiding complex and laborious surgery and ventricular endoscopy is a suitable procedure to obtain tissue samples with low complications rate (19).

Second most common lesions are represented by glial tumors that include pure pineal astrocytomas and astrocytomas that invade the posterior 3rd ventricle from the surrounding structures such as brainstem and thalamus (21). Usually they are low grade lesions (grade 1 pilocytic and grade II fibrillary astrocytomas) as in our series cases 3 and 11, that have all the characteristic features of LGG: localization at the

level of quadrigeminal plate and the absence of contrast enhancement. They are benign, indolent lesions and the treatment of choice is treatment of hydrocephalus and close imagistic follow-up (21), biopsy seldom being necessary as in case 3 where the imagistic appearance, contrast enhancing lesions suggested a more aggressive lesion.

The ETV has a high rate of success in treating obstructive hydrocephalus caused by lesions in the posterior 3rd ventricle with an estimated rate of 87% (22), being the most physiological method of CSF derivation and preventing the installation of a ventriculoperitoneal drainage system with its known complications (infection, obstruction, malfunction, over drainage, hardware failure) (23).

In our series, 19 patients had a successful ETV with a success rate of 95% at 6 months one case had a closure of the stoma at 3 months and needed a new surgical procedure to redo the ETV, interestingly in this case the closure of the stoma was due to tumoral carcinomatosis at the level of prepontine cistern, observed intraoperative but not on preoperative MRI images case 7 (fig. 2).

CONCLUSIONS

Ventricular endoscopy is a safe and reliable technique for the management of the posterior 3rd ventricle lesions. Trough ETV allows the treatment of hydrocephalus with high rates of success in a physiologic fashion and with no need for additional shunting.

The endoscopic biopsy allows safe sampling of the lesion, in the same surgical procedure with ETV, for accurate pathologic exam, thus avoiding further surgical intervention.

BARIATRIC AND METABOLIC SURGERY IN TIME OF COVID-19 PANDEMIC

The coronavirus pandemic is a source of unprecedented pressure on the health-care systems, including disrupting bariatric and metabolic surgery. Like most elective surgery, bariatric and metabolic procedures are being postponed worldwide during the pandemic. With the outbreak, numerous of people seeking these operations will exist. Many candidates for bariatric and metabolic surgery are at high risk of morbidity and mortality from comorbid conditions. For these patients, access to surgical treatment should be prioritized based on disease-focused clinical needs, rather than weight-centered approach, to reduce harm from delaying surgery. Disease-oriented, medically meaningful strategies to triage patients seeking metabolic surgery after the COVID-19 crisis should help prioritize patients in more urgent need, both now and long into the future. (Rubino F, Cohen R, Mingrone G, *et al*. Bariatric and metabolic surgery during and after the COVID-19 pandemic: DSS recommendations for management of surgical candidates and postoperative patients and prioritization of access to surgery. *Lancet Diabetes Endocrinol* 2020; 8: 640-648).

MULTIPLE CEREBRAL VASCULAR MALFORMATIONS IN SAH – WHAT IS THE ROLE OF ANGIOGENESIS?

MULTIPLE CEREBRAL VASCULAR MALFORMATIONS IN SUBARACHNOID HEMORRHAGE – WHAT IS THE ROLE OF ANGIOGENESIS? (Abstract): Subarachnoid hemorrhage (SAH) is a very serious form of cerebral hemorrhagic stroke, with devastating potential. The multiplicity of cerebral aneurysms in patients that suffer from SAH is a known fact, but all scientific date available today puts it on the same risk factors as for having one single ruptured aneurysm: gender, age, smoking status, ethnicity. We noticed that certain vascular complications tend to occur more frequently in patients with multiple intracranial vascular lesions. **Material and methods:** Data were collected from the Department of Neurosurgery I of the University Emergency Hospital of Bucharest archive from 2017 to 2020. We selected for this study a group of 147 patients hospitalized for SAH and treated in this service during the said period of time. **Results** included strong positive correlations with *Pearson* R coefficient higher than 0.4 between pertaining to the group with multiple brain aneurysms/cerebral vascular malformations and developing re-permeabilization of the previously secured aneurysm, ocular complications (bleeding), DVT/PE, symptomatic vasospasm or hematoma at arterial puncture site during hospitalization for this pathology. We investigated the pattern of those complications and their possible causes and a link between angiogenesis, vascular endothelium and the studied complications seems to be present. Functional outcome scores depending on the multiplicity of the lesions and their differences were also investigated. **Conclusions:** The nature of multiple intracranial vascular lesions in the subjects of the current study cannot be attributed to connective tissue disease. Given these aspects, it can be stated that the profile of these complications suggests, rather than a defective structure of the vascular wall, a defect in the intimal endothelial layer of the vascular wall. **Keywords:** SAH, MULTIPLE ANEURYSMS, VASCULAR LESIONS, VASCULAR COMPLICATIONS, ANGIOGENESIS, VASCULAR ENDOTHELIUM.

In this present study, the starting idea came from an empirical clinical observation resulting from daily activity in the neurosurgery clinic, following careful revision of the parameters of hospitalized patients with subarachnoid hemorrhage (SAH). We noticed that, in patients with similar metabolic profile and similar ethnographic characteris-

tics, with SAH of fairly similar etiology (hypertensive, idiopathic, aneurysmal or by cerebral AVM) and belonging to similar Hunt and Hess (1968) (1) and modified Fischer scale (2006) groups (2), some of them developed vascular complications with a major impact, while for the group with unique vascular intracranial malformation the clinical evolution remains unmarked by such events.

This observation has led to the need to identify other factors, independent of the above, which may be incriminated for the development of these complications.

Currently there is data in the literature that attributes the multiple character of cerebral vascular malformations (mainly aneurysms) to female patients who smoke (3), but there are very few studies on the evolving complications of this type of patients and there are also studies that refute association of smoking with increased risk of complications or poorer prognosis in SAH (4). Out of a desire to distance ourselves from this association, which could sometimes pass as a stigma capable of distancing the researcher from the depth of the problem, we chose to investigate whether there is an association with statistical significance between belonging to the group with multiple cerebral vascular malformations and the development of certain vascular complications in the presence of SAH and whether we can find new risk factors to explain the association.

MATERIAL AND METHODS

The present study is a descriptive clinical study with a retrospective and prospective approach, conducted in the Neurosurgery Clinic, Department of Neurosurgery I of the University Emergency Hospital of Bucharest. We selected the group of patients hospitalized for SAH and treated in this service for a period of four years (01.01.2017-31.12.2020) and we followed the patients from discharge for a period of three years (01.10.2018-30.09.2021). Selection criteria were rigorously applied. The prospective approach includes was designed for the monitoring of patients through a series of parameters that are the subject of personal study.

We centralized the following data in this chapter: the single or multiple character of the intracranial vascular malformations, the type of complications suffered during hospitalization, GOS score at discharge and follow-up visits.

Out of the 147 patients with aneurysmal SAH, 36 were diagnosed angiographically or by computerized tomography angiography (CTA) scan with more than one aneurysm or multiple vascular malformations. The vascular complications that will be studied are the ones with the highest occurrence rates among the group of subjects with multiple intracranial vascular malformations. We summarized them in table I. For systemic complications such as metabolic imbalances, fever, infections or hospital acquired pneumonia, the rate of occurrence was similar in the two groups.

We made use of *Pearson's* Chi-square test as a statistical test applied to categorical data sets. It offers high values of Pearson's coefficient and probability rate, in a proportional manner to the strength of the association (< 0.2 – positive but weak correlation, > 0.2 – strong correlation, >04.- very strong correlation). The *McNemar* test was used to evaluate the association between paired variables (4). The *ANOVA* one-way test was used to compare the aver-

age values of two groups and the statistical significance of the difference.

RESULTS

In the group of 147 patients hospitalized for aneurysmal SAH, 36 (24.48%) were diagnosed angiographically or by angio-CT with aneurysms or multiple vascular malformations. This result is consistent with recently published data, which estimates that in one-fifth of patients with cerebral aneurysms this malformation is multiple (3). The summary of these data is exemplified in the first figure.

Regarding the ethnographic data, the average age in the group of those with multiple cerebral vascular malformations was 51 years old (min = 30, max = 67), with a sex ratio F: M 6.2: 1.

The following aspects were observed directly based on descriptive statistical data: complication rate, type of complications (vascular or non-vascular) and the association between belonging to the group of subjects with simultaneous intracranial vascular malformations and the development of vascular complications (tab. I)

The *Pearson* R coefficient of 0.455867 and p value for *McNemar*'s association test of 0.001 indicates a very strong positive correlation between belonging to the group with multiple vascular aneurysms/ malformations and the development of vascular complications if the subject suffers a subarachnoid hemorrhage (fig. 2).

We thus obtained strong positive correlations, with a *Pearson* R coefficient greater than 0.4 for the following associations: belonging to the group of subjects with multiple intracranial vascular malformations and developing symptomatic cerebral vasospasm, hematoma at the site of arterial puncture for angiography, development of thrombosis of cerebral veins or arteries, ocular complications. This risk of aneurysmal re-permeabilization could be underestimated because patients are still being followed and some of the re-permeabilizations may have not yet been diagnosed (tab. II).

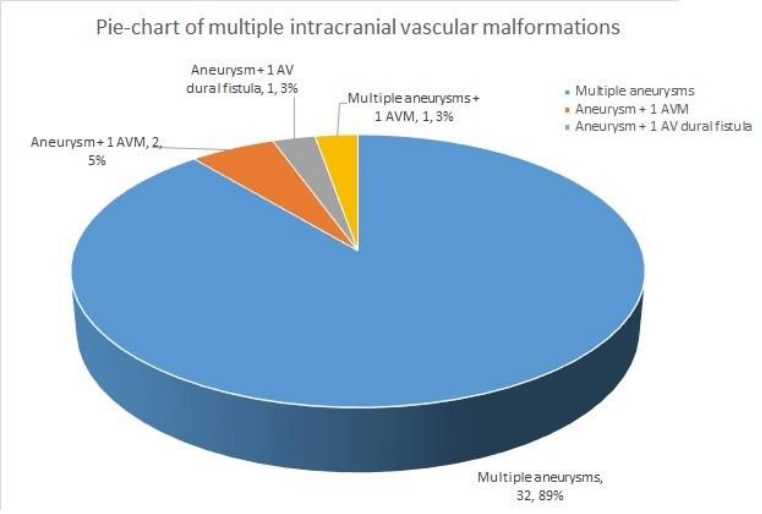

Fig. 1. Subjects with multiple intracranial vascular malformations. Designed based on personal study's results using *MicrosoftExcel*

TABLE I.

Summary of vascular and non-vascular complications suffered by subjects in our study. Results based on personal study using *Minitab software*

	Complication	Multiple aneurysms / cerebral vascular malformations group (36)	Unique aneurysm (111)
Vascular	Rebleeding	3 (8.33%)	1 (0.90%)
	Symptomatic vasospasms	16 (44.44%)	27 (23.42%)
	Ocular complications	5 (13.88%)	1 (2.80%)
	Intracerebral hematoma	4 (11.11%)	4 (3.60%)
	Hematoma at puncture site	3 (8.33%)	0 (0%)
	Re-permeabilization of the aneurism	3 (8.33%)	1 (0.90%)
	Transient ischemic stroke	2 (5.55%)	1 (0.90%)
	Thrombosis of cerebral arteries or veins	4 (11.11%)	3 (2.70%)
	DVT/PE	4 (11.11%)	2 (1.80%)
Nonvascular	Infections	1 (2.77%)	3 (2.70%)
	Significant metabolic imbalances	2 (5.55%)	7 (6.30%)
	Others (including non-coronary cardiac complications)	6 (16.66%)	28 (25.22%)

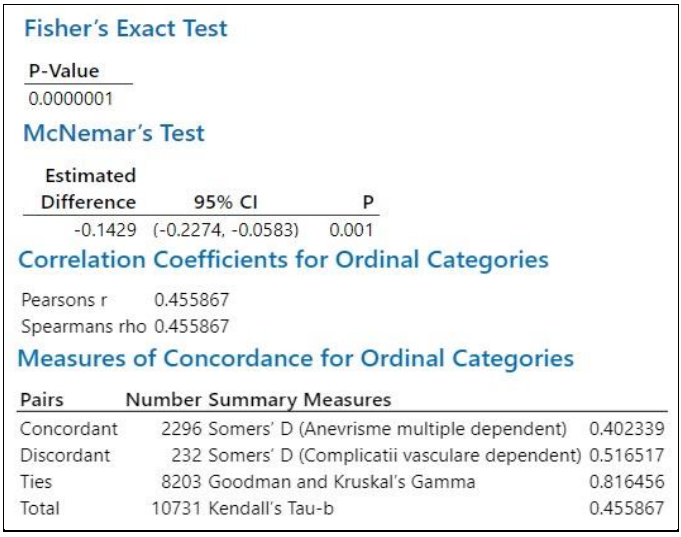

Fig. 2. Association tests between multiple intracranial vascular lesions and vascular complications development in patients who suffered A SAH. P values < 0.005 indicate that the null hypothesis is false and thus there's very little change that the investigator be wrong when assessing there is a correlation between the variables tested.
Results based on personal study using *Minitab software*

TABLE II.

Summary of statistical analysis parameters run for each vascular complication. Results based on personal study using *Minitab software*

Complications	95% C.I. - *McNemar* test	*McNemar* test – p value	*Fischer's* exact test - p value	Pearson R coefficient value
Rebleeding	(0.1416, 0.2938)	p<0.005	0.0456002	0.196447
Symptomatic vasospasm	(-0.1378, 0.0562)	0.461	0.0199008	0.200100
Ocular complications	(0.1123, 0.2687)	p<0.005	0.0216543	0.212052
Intracerebral hematoma	(0.1098, 0.2711)	p<0.005	0.100841	0.142317
Hematoma at puncture site	(0.1502, 0.2987)	p<0.005	0.0137661	0.253448
Re-permeabilization aneurysm	(0.1416, 0.2938)	p<0.005	0.0456002	0.196447
Transient ischemic stroke	(0.1477, 0.3013)	p<0.005	0.148593	0.141566
Thrombosis of cerebral arteries or veins	(0.1269, 0.2813)	p<0.005	0.0319193	0.202323
DVT / PE	(0.1329, 0.2888)	p<0.005	0.0945758	0.154953

We obtained further positive but weak correlations, with a *Pearson* R coefficient greater than 0.2 and less than 0.4 for the following associations: belonging to the group of subjects with multiple intracranial vascular malformations and aneurysmal rebleeding, aneurysmal re-permeabilization, developing deep venous thrombosis (DVT) or pulmonary thromboembolism (PE) during hospitalization for SAH, intracerebral hematoma formation and transient ischemic attacks (TIAs) development during hospitalization for SAH.

The one-way *ANOVA* test was run for the comparison of the averages of 2 groups: the group of subjects with a single aneurysm and the group of subjects with multiple cerebral vascular malformations, respectively, in terms of functional status scores at discharge and follow-up visit (3-6 months).

When calculating the average *Glasgow Outcome Score* (GOS) at discharge, we obtained a higher average value among those with a single intracranial vascular malformation than for those with multiple lesions of this type (3,865 *vs.* 3,694), the difference being 0.171.

A similar positive difference of 0.139 was obtained for the GOS averages at follow-up visit (4,306 *vs.* 4,167). However, the value of the parameter F being subunit in both cases (F = 0.50 for GOS at discharge and 0.34 for GOS at follow-up) and providing p values greater than $\alpha = 0.05$ (p = 0.428 and p=0.559 respectively), means that the null hypothesis cannot be rejected, the conclusion being that we do not have enough evidence that there is a statistically significant difference between the means of the two groups regarding GOS values at neither discharge, nor follow-up (tab. III).

TABLE III.

ANOVA* one-way test results for the average GOS at discharge and follow-up for the two groups. Results based on our study using *Minitab software

ANOVA one-way, α=0.05	GOS at discharge	GOS at follow-up
F parameter	F=0.50<1	F=0.34<1
p value	p=0.428	p=0.559

DISCUSSION

Comparing the two groups of subjects in terms of complications - those with a single aneurysm and those with multiple vascular intracranial aneurysms/ malformations, we can make the following statements after running analytical statistics tests:

• Subjects with a single intracranial vascular malformation suffered to a lesser extent from vascular complications such as those described;

• Strong positive correlations were obtained between belonging to the group with multiple intracranial malformations and the risk of developing: Hematoma at the site of the arterial puncture deep venous thrombosis (DVT) / pulmonary thromboembolism (PE), re-permeabilization of the previously secured aneurysm, ocular complications (bleeding), symptomatic vasospasm, hematoma at arterial puncture site;

• Positive correlations, although weaker than those mentioned in the previous paragraph, were obtained between belonging to the group with multiple intracranial malformations and the development of the following: cerebral arteries or veins thrombosis, intracerebral hematoma, symptomatic vasospasm, TIAs.

Regarding the GOS on discharge and follow-up visit (3-6 months), the average scores of the group with a single aneurysm was higher than that of the group with multiple cerebral vascular malformations, but the statistical significance of these results could not be demonstrated.

CONCLUSIONS

The nature of multiple intracranial vascular lesions in the subjects of the current study cannot be attributed to connective tissue disease (6), none of the 36 subjects being known to have had such a condition and showing no clinical signs to suggest such a pathology.

Given these aspects, it can be stated that the profile of these complications suggests, rather than a defective structure of the vascular wall, a defect in the intimal endothelial layer of the vascular wall. This observation is made due to the fact that some complications such as thrombosis, ischemia, bleeding - are closely related to the reactivity of the vascular endothelium and given that this layer of endothelial cells is the source of synthesis and release into the systemic circulation of a large number of prothrombotic and antithrombotic factors, and proinflammatory and anti-inflammatory factors whose imbalance favors and promotes such complications (7).

Whether the vascular wall or intimal layer of cells defects are congenital or achieved, pursuing further studies aimed at them is equally important because it would provide for potential targeted therapy. Given the previous observation, as well as the model of the rate of occurrence of vascular complications among the presented subjects, we consider it imperious that further studies be conducted in order to investigate issues related to vascular endothelium and angiogenesis in patients with simultaneous intracranial vascular malformations (8).

There are recent studies regarding post-SAH vascular endothelium and its connection to local phenomena such as vasospasm, early brain injury, disruption of the blood-brain barrier and cytotoxic and vasogenic edema (9), but vascular complications at other sites (ocular bleeding, DVT/PE, re-permeabilization of the aneurysm) are still poorly studied (6).

Furthermore, if the role of the endothelial cells in promoting local destructive phenomena is well established, then what happens if SAH occurs on previously dysfunctional ves-

sel wall or endothelium? We did not find recent data in the literature that refer to the quality of the arterial wall or the intrinsic characteristics of the vascular endothelium and its role in the prognosis of patients with SAH.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

NEWS

BIFIDOBACTERIUM LONGUM: PROTECTION AGAINST INFLAMMATORY BOWEL DISEASE

The prevalence of inflammatory bowel disease is generally associated with the change of the immune system and gut microbiota. Bifidobacterium longum is a symbiotic bacterium existed in the human gastrointestinal tract and has been demonstrated to be capable of relieving colitis in mice and can be employed as an alternative or auxiliary way for treating inflammatory bowel disease. Bifidobacterium longum can change the structure of the gut microbiota, induce and regulate immune responses, and reduce the expression of inflammatory cytokines and reactive oxygen species in the intestine. Besides, it can also maintain the normal intestinal barrier function by increasing the expression of the tight junction protein. Therefore, Bifidobacterium longum has great potential and can be used as a prevention, replacement, or adjuvant treatment for inflammatory bowel disease. (Yao S, Zhao Z, Wang W, Liu X. Bifidobacterium Longum: Protection against Inflammatory Bowel Disease. J *Immunol Res.* 2021 Jul 23;2021:8030297).

BEYOND DYSPHAGIA: RESULTS OF A SURVEY AMONG ROMANIAN GASTROENTEROLOGISTS REGARDING THEIR DIAGNOSIS AND MANAGEMENT OF EOSINOPHILIC ESOPHAGITIS

BEYOND DYSPHAGIA: RESULTS OF A SURVEY AMONG ROMANIAN GASTROENTEROLOGISTS REGARDING THEIR DIAGNOSIS AND MANAGEMENT OF EOSINOPHILIC ESOPHAGITIS (Abstract): Eosinophilic esophagitis (EoE) is a chronic, immune-mediated disease characterized by symptoms of esophageal dysfunction and eosinophil-predominant inflammation on esophageal biopsies. EoE prevalence increased in recent years and nowadays it is recognized as a common cause of dysphagia and food impaction. Despite the publication of updated guidelines, multiple studies reported variable clinical practices regarding the management of EoE patients. The **aim** of this study was to assess the adherence to published guidelines and the current clinical management of EoE among gastroenterologists from three academic centers in Romania. **Material and methods:** We performed a cross-sectional study of 62 gastroenterologists using a 12-item questionnaire probing the clinicians' understanding of EoE diagnosis and therapeutic guidelines. The online survey was conducted between 15th of February and 15th of March 2022 and the data was processed using SurveyPlanet. **Results:** The overall completion rate was 100% and the mean time of completion was 8.2 minutes. Most participants (70.9%) were gastroenterologists from Institute of Gastroenterology and Hepatology in Iasi Romania. The rest were from academic centers like Bucharest (19.3%) and Timisoara (9.6%). Regarding the understanding of the published EoE guidelines, only 30 respondents (31.6%) were aware that dysphagia and food impaction can be suggestive of EoE and are required diagnostic criteria. All the gastroenterologists agreed that eosinophil-predominant inflammation on esophageal biopsy is a mandatory criterion for EoE diagnosis. The exclusion of secondary causes of esophageal eosinophilia was considered necessary for EoE diagnosis by 42 survey participants (48.3%), while the other gastroenterologists found the differential diagnosis helpful, but optional. The majority agreed to the necessity of a minimum of 6 esophageal biopsies in order to increase the diagnostic yield of EoE, while 16.1% thought a minimum of 2 biopsies to be enough. The preferred first line treatment was proton pump inhibitors (PPI) for 41.9 % and topical steroids for 48.4 % of respondents. Twenty-nine participants (46.8%) considered follow-up with endoscopy and biopsies after a course of 6-12 weeks of therapy in order to evaluate remission, while 22 (35.5%) would not repeat endoscopy in case of symptom resolution. **Conclusions:** Among gastroenterologists, the adherence of Romanian gastro-enterologists to published EoE guidelines seems to vary considerably, especially regarding PPI use and assessing response to therapy. Targeted strategies are needed to reduce discrepancies in clinical practice, starting with interventions to increase clinical awareness in order to optimize the management of EoE patients. **Keywords:** EOSINOPHILIC ESOPHAGITIS, DYSPHAGIA, ESOPHAGEAL BIOPSIES, GUIDELINES ADHERENCE.

Eosinophilic esophagitis (EoE) is a chronic, immune-mediated condition that features symptoms of esophageal dysfunction such as dysphagia and food impaction in adults. The first description of EoE as a distinct entity, different to gastroesophageal reflux disease and achalasia, was made by Attwood *et al.* in 1993 (1). Since then, the epidemiology of EoE has evolved substantially and multiple studies have been reporting increased prevalence (2-4), making so that EoE is now recognized as a leading cause of dysphagia. For instance, according to a study by Prasad et al., the EoE incidence in Minnesota, USA, rose from 0.35 cases/100,000 people to 9.5 cases/100,000 people over a 15-year period (2). Similarly, in Denmark, Dellon *et al.* reported an increased annual incidence rate from 0.13/100.000 in 1997 to an annual incidence rate of 2.6/100,000 in 2012 (3).

The first consensus guidelines for the diagnosis and treatment of EoE were published in 2007 and subsequently updated in 2018 and then in 2020 (5-7). The EoE diagnosis is based on symptoms of esophageal dysfunction and esophageal mucosal biopsies with ≥15 eosinophils per high power field (eos/HPF). Until recently, consensus guidelines recommended as the first diagnostic step a trial of proton pump inhibitor (PPI). The latest guidelines now recommend PPI therapy not as a diagnostic criterion, but rather a first-line therapeutic agent in newly diagnosed patients with EoE (6, 7). Topical steroids and elimination/elemental diets can be also considered treatment options. With regard to treatment endpoints, the most commonly assessed outcome is histological, clinical and endoscopic remission.

Despite the publication of updated guidelines, clinical practice related to the management of EoE patients has been proven variable (8-10). In this context, we aimed to assess gastroenterologists´ adherence to the latest guidelines and the current clinical management of adult EoE patients in three academic centers from Romania.

MATERIAL AND METHODS

This was a cross-sectional study into the adult EoE patient evaluation and management practices of Romanian gastroenterologists using a web-based survey conducted between 15th of February and 15th of March 2022.

The survey instrument consisted of 12 targeted questions about the respondents' knowledge of published guidelines related to the diagnosis and management of EoE, and also scenario-based clinical judgment questions. The first six questions assessed the physicians' general perception regarding the clinical symptoms, the endoscopic and the histologic diagnosis of EoE. The next questions focused on the therapeutic management and follow-up of EoE patients.

Participation was voluntary. The survey could only be accessed via an email link, and all responses were anonymous. Data recording and processing was performed using SurveyPlanet. The study was conducted in accordance with the Declaration of Helsinki.

RESULTS

The web-based survey was completed by 62 gastroenterologists with a completion rate of 100% and a median completion time of 8.2 minutes. Survey respondents were mostly female (59.6%). The majority (70.9%) were gastroenterologists from the

Institute of Gastroenterology and Hepatology in Iași, Romania. The others were from academic centers like Bucharest (19.3%) and Timisoara (9.6%).

The number of EoE patients managed annually by survey participants differed from 1 to 5 patients in 56.5% of respondents, 6-19 patients in 4.8%. Only 1 participant reported managing between 20-50 patients with EoE annually.

EoE diagnosis

Concerning the understanding of EoE published guidelines, 31.6% of gastroenterologists founds the clinical symptoms of dysphagia and food impaction necessary for diagnosis, while 65.3% reported that symptoms were helpful, but not mandatory clues. However, all the participants agreed that the presence of eosinophil-predominant inflammation on esophageal biopsies (>15 eosinophils/high-power field) was a required criterion for a definitive diagnosis of EoE. Likewise, almost all gastroenterologists (82.3%) agreed to the necessity of a minimum of 6 esophageal biopsies taken from the proximal and distal esophagus in order to increase the diagnostic yield of EoE. In addition, only 48.3% of participants considered it of major importance to exclude other causes of esophageal eosinophilia, including gastroesophageal reflux disease, and 34.5% did not find this necessary for EoE diagnosis (fig. 1).

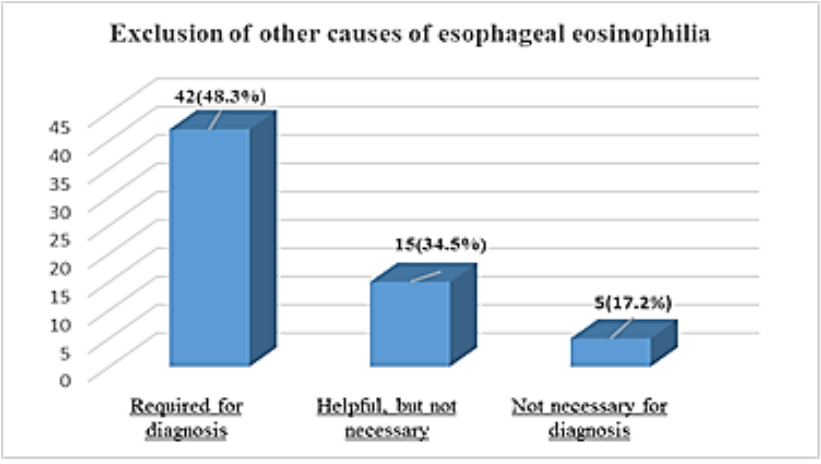

Fig.1. Knowledge of EoE published guidelines regarding diagnosis

EoE treatment and monitoring

When asked about treatment options for patients diagnosed with EoE, 41.9% of respondents reported using as first-line therapy a high-dose PPI regimen, while 48.4% indicated the use of topical steroids. Only 8.1% of participants preferred to start the patient on an elemental/elimination diet (fig. 2). In case of esophageal stricture, management by means of endoscopic dilation was considered safe and efficient by 56.5% of gastroenterologists. However, 43.5% of participants associated endoscopic dilation with a higher risk of perforation. In addition, when suspecting EoE, 67.7% of participants considered an initial trial of PPI useful before trying other diagnostic strategies.

In order to determine the success of therapy, 35 gastroenterologists (56.5%) considered it imperative to repeat endoscopy with biopsies to assess histologic remission, while 19 (30.6%) would not repeat endoscopy in the presence of symptoms resolution, and 8 (12.9%) would repeat endoscopy only to assess endoscopic remission (fig. 3).

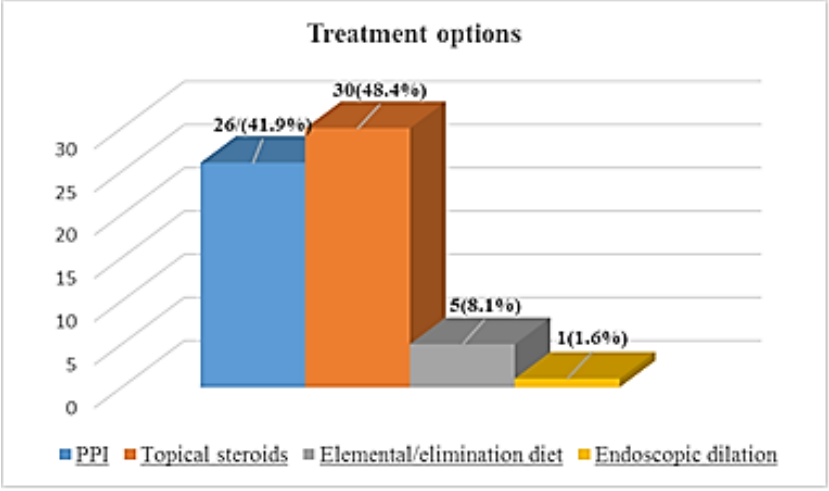

Fig. 2. Treatment options for EoE patients

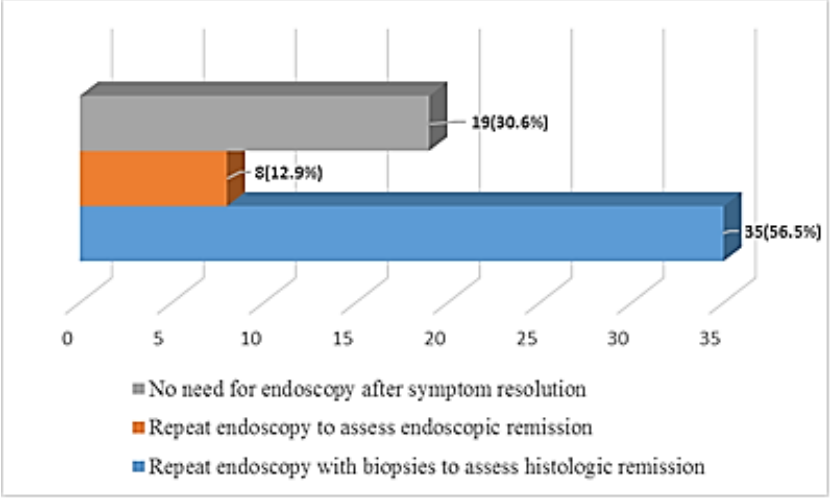

Fig. 3. Assessing the response to therapy

Last but not least, about monitoring patients' responses to therapy, 29 survey participants (46.8%) would consider follow-up with endoscopy and biopsies after a course of 6-12 weeks of therapy in order to evaluate remission, while 22 (35.5%) would not repeat endoscopy in the presence of symptom resolution.

DISSCUSION

To our knowledge, this is currently the first survey regarding the EoE diagnosis and management practices of gastroenterologists in our country. Given the indications of variable EoE management internationally despite updated published guidelines, our study provides insight into the adherence of Romanian gastroenterologists to available EoE guidelines.

While there is a lack of epidemiological data of EoE in Romania, our results suggest a possible low incidence of EoE cases, as more than half of the participating gastroenterologists reported diagnosing a maximum of five new EoE patients annually.

When a patient presents complaining of dysphagia or food impaction, only 31.6% of gastroenterologists are aware that these symptoms can be suggestive of EoE, and that they are, in fact, compulsory diagnostic criteria for EoE. These findings indicate a real need for to improve clinical awareness to avoid misdiagnosis.

Regarding the clinicians' knowledge of published guidelines, our survey further showed that, while all survey participants agreed that eosinophil-predominant inflammation on the esophageal biopsy is a mandatory criterion for EoE diagnosis, only 48.6% considered it necessary for diagnosis to exclude other causes of esophageal eosinophilia, including gastroesophageal disease. This emphasizes the importance of a complete and accurate differential diagnosis in order to confirmed EoE.

Despite the updated published guidelines that underline the need to remove PPI trials from the diagnostic criteria (6, 7), our survey revealed that approximately 70% of gastro-enterologists would still recommend a trial of PPI before any other strategies in case of suspected EoE.

Concerning treatment options, PPI and topical steroids are recommended in relatively equal proportions according to our survey, which is in accordance with existing guidelines (6, 7). However, very few Romanian gastroenterologists would initiate an elemental/elimination diet as first-line treatment for EoE. This reluctance may be justified by the arguably poor compliance of Romanian patients to dietary restrictions and also by the current shortage of trained nutritionists in our country.

Multiple studies reinforce international guidelines with regard to the need of clear therapy endpoints for patients diagnosed with EoE, histological remission being the most important one (6, 7, 11-13). Our survey revealed that most of the participating gastroenterologists (56.5%) considered it essential to repeat endoscopy with esophageal biopsies in order to assess histological remission. However, there is still a sizeable proportion of healthcare providers (30.6%) who do not consider the endoscopic reevaluation necessary in case of symptom resolution. These variations in Romanian practitioners' adherence to guidelines are important indicators of EoE patient follow-up practices that prioritize symptomatic manifestations.

CONCLUSIONS

Our survey found differences in the diagnosis and management of patients with EoE in Romania, particularly regarding the use of PPI trials in case of suspected EoE, and also in appreciating the need of repeat endoscopies with histology to monitor response to therapy. As these findings are in contrast with the latest international guidelines, our survey highlights the need for intensified education and development of targeted strategies in order to raise clinicians' awareness and optimize the clinical management of EoE patients.

CONFLICT OF INTEREST AND FUNDING

The authors declares that there is no conflict of interest, and they received no specific funding regarding this scientific research.

URETEROHYDRONEPHROSIS AND KIDNEY STONE COMPOSITION: POTENTIAL PREDICTING FACTORS FOR THE FAILURE OF EXTRACORPOREAL LITHOTRIPSY (Abstract) **Aim:** The objective of our study was to identify the factors that predict the failure of extracorporeal lithotripsy in the treatment of ureteral stones, with reference to the ureteral obstruction and composition of stones determined by infrared spectroscopy. **Material and methods**: We conducted a retrospective study, evaluating stone-free rates of extracorporeal lithotripsy in patients with ureteral lithiasis. The stone examination was made by infrared spectroscopy. **Results**: 215 patients were included in this study. The overall stone-free rate in this study was 79.06%. The presence of ureteral obstruction consecutive to stones correlates with lower stone-free rates in comparison to patients without ureterohydronephrosis. Calcium oxalate monohydrate stones had lower fragmentation rates (37.5%) compared to calcium oxalate dihydrate (84.69%) and uric acid stones (85.71%). In this study, age and gender are not factors that influence the effectiveness of extracorporeal lithotripsy. **Conclusions**: Extracorporeal shockwave lithotripsy is an effective method to manage ureteral lithiasis, but it is limited by numerous factors: body mass index, the presence of ureteral obstruction, as well as by the biochemical composition of stones. Impacted stones for a long period and the main component of calcium oxalate monohydrate have fewer chances to be successfully fragmented. **Keywords**: SHOCK WAVE LITHOTRIPSY, URETERAL STONES, STONE COMPOSITION, URETERAL OBSTRUCTION, INFRARED SPECTROSCOPY.

Urinary lithiasis is one of the most common chronic urological conditions with a prevalence in Europe estimated at approximately 4% (1). Despite the important technological progress in endourology, extracorporeal shock wave lithotripsy (ESWL) is still one of the most important methods used in managing kidney stone disease that is currently in the arsenal of urologists, due to its safety profile and minimal invasiveness.

The European Association of Urology Guidelines currently recommends ESWL for the treatment of lithiasis, regardless of a stone's topographical in the ureter.

The efficiency of *in situ* ESWL for ureteral stones has been reported by various authors as ranging between 80-95% (2, 3, 4).

In addition to the technical parameters of the lithotripter, the efficiency of ESWL is conditioned by anatomical factors (body mass index, skin-to-stone distance, and ureteral wall thickness) and by stone properties (stones' chemical composition, the degree of impaction in the ureteral mucosa).

The influence of the ureteral obstruction on the effectiveness of ESWL for ureteral stones is still a controversial subject and this become one of the main goals of our research.

MATERIAL AND METHODS

We have conducted a retrospective study from January 2021 to January 2022, that included patients treated in the Department of Extracorporeal Lithotripsy of "Dr. C. I. Parhon" Hospital in Iasi. All ESWL procedures were performed by a urologist with significant experience in this field.

The patients were investigated by ultrasound to determine the degree of ureteral obstruction and, if possible, to determine the stones' size and position. Intravenous urography was performed in selected patients. The exclusion criteria were the presence of a ureteral stent, blood clotting disorders, inflammatory syndrome, and multiple ureteral calculi.

The procedures were performed with Dornier Sigma Compact electromagnetic lithotripter, and the stones were detected by X-Ray. The maximum number of shock waves per session was 2900 with a frequency of 70 shock waves per minute. Local analgesia was obtained by topical application of a gel containing piroxicam, lidocaine and cyclobenzaprine, 20 minutes before the procedure. Only in 15 cases, upon request, we have administrated 1 ampoule of Tramadol, 100 mg intramuscularly in order to continue the procedure.

The symptoms associated with the removal of lithiasis fragments were of moderate intensity, under treatment with non-steroidal anti-inflammatory drugs and alpha-blockers (Tamsulosin) and they did not require a form of urinary drainage (ureteral stenting or percutaneous nephrostomy).

The postprocedural evaluation was conducted 3-4 weeks after extracorporeal lithotripsy and it included control reno-vesical radiography (KUB) and ultrasound. The presence of fragments larger than 7 mm with or without ureterohydronephrosis after lithotripsy was considered a failure of treatment and the patients accepted the second session of ESWL or retrograde ureteroscopy.

Stones' composition was determined by infrared spectroscopy (FTIR) with the Brucker Alfa II spectrophotometer.

The ethical approval for this study was obtained from the Institutional Ethics Committee of "Dr. C. I. Parhon" Clinical Hospital (No. 3530/ 06.05.2022). All the methods that we used comply with relevant guidelines and regulations.

The results were processed and analyzed using statistical *SPSS software version 27.0*, IBM Corporation. Chi-squared test (χ^2) and t-test were applied. A result of $p<0.05$ was accepted as statistically relevant.

RESULTS

During the above-mentioned period, 319 patients with ureteral lithiasis were evaluated, but after applying the exclusion criteria, 215 patients were included in our study, aged 19-73 (the average age was 50.32, SD 12.14 years).

Table I shows the results of the compar-

ative analysis of the two groups, related to the demographic characteristics, the chemical composition of the stone, the location of the stone and the personal history of urinary lithiasis. Among the six analyzed elements, four reached the limit of statistical significance (body mass index, degree of ureteral obstruction, stone's composition and location in the ureter), one element (history of the urinary stones) had a borderline value, and one element was not statistically significant (patient's gender).

*Significant (p-value<0.05). Chi-Square tests were used. COD – Calcium Oxalate Dihydrate; COM – Calcium Oxalate Monohydrate; UA – Uric Acid; CA – carbapatite; STRU – Struvite.

Figure 1 shows stone-free rates according to the chemical composition determined spectroscopically. We noticed that stones with COM as the main component have the lowest probability of being stone-free, while for the other types of stones, the rates of fragmentation are similar. No patients with cystine or brushite calculi were reported in this group.

Table II shows no significant differ-

ences regarding certain parameters: patients' age, irradiation dose and the number of sessions required to reach stone-free status, between the two groups of patients. On the other hand, patients in whom ESWL did not result in stone fragmentation had an average stone size of 10.37 mm compared to 8.97 mm, the difference being statistically significant (t=2.556, p=0.013).

DISCUSSION

In this study, we tried to identify the factors that can be associated with the failure of first *in situ* ESWL in the treatment of ureteral stones, especially the presence of the ureteral obstruction and the specific accurate composition of stones.

Despite the important progress made in the field of endourology, ESWL is still one of the most feasible ways to manage ureteral stones, due to its low costs and favorable clinical results (7).

Various studies regarding the success of ESWL for ureteral stones have been pub-

lished. The data published by Seitz *et al.* reveal that the general stone-free rate obtained in a group of 130 patients with ureteral lithiasis was 77.4%, but another research, published by Mogensen *et al.* , found much higher rates, respectively 91.1% for lumbar ureteral stones, and 90.9% in the case of stones located in the iliac or pelvic segment of the ureter, whereas similar success rates were demonstrated by Chang *et al.* , respectively 81.9% (8). The stone-free rate for the patients included in this study is 79.06%, falling within the reference ranges of similar studies.

Previous studies have demonstrated that the success of ESWL depends on numerous factors, among which the most important are stone location and density, skin-to-stone distance (SSD), and BMI. As for the influence of age on ESWL success rate, in a comparative retrospective study, Halachmi *et al.* found stone-free rates of 91% for elderly patients and young patients. The efficiency profile of ESWL in elderly patients is also proved by data published by Delakas *et al.* (9, 10).

Yet, the research conducted by Ikegaya contradicts this statement: its results prove that the success rate of ESWL in elderly patients is lower in comparison to young patients (11). Ng *et al.* found that lithotripsy is less effective in elderly patients with renal lithiasis, but the differences are not statistically significant concerning ureteral lithiasis (12). In our study, we did not find significant differences regarding age in the chances for stone-free status (p=0.755)

In addition, we also found that there is no statistically significant difference in the correlation between personal history of lithiasis and the stone-free rate after ESWL, as the value obtained is borderline (p=0.0517).

Previous studies have demonstrated a strong relationship between the efficiency of stone fragmentation by ESWL and patients' BMI. In a group of 100 patients with ureteral stones measuring 5-10 mm, Pareek *et al.* found that the BMI is an independent predictive factor for the stone-free rate and that obese patients most likely need an endoscopic intervention in the context of the failure of ESWL (13). These data are also supported by Yang *et al.* , who demonstrated, in a group of 203 patients, that extracorporeal lithotripsy's probability of success is twice lower in the case of obese and overweight patients, in comparison to normal weight patients (14). A study conducted in France showed that the efficiency of ESWL in obese patients, with an average BMI between 35 and 40 kg/m^2, is around 60%, and it decreases in direct proportion to its increase. For patients with a BMI of 45-50 kg/m^2, the efficiency is 33.3%, and for patients with BMI greater than 50 kg/m^2, the efficiency is only 20% (15). Paradoxically, Delakas *et al.* , in their studies, note that a BMI above normal values does not negatively influence the efficiency of ESWL (10).

In this group of patients, we observed that the highest stone-free rate was obtained in patients with stones located in the lumbar segment of the ureter (84.72%) in comparison to stones located in the iliac ureter (62.5%) and the pelvic ureter (69.09%), respectively. The data identified by us are also supported by other studies in the literature. Delakas identifies a stone-free rate of 61.5% for stones located at the level of the pelvic ureter, 75.6% for iliac stones and 82.9% for lumbar ureteral stones (10). However, there is no consensus

in the literature about the importance of stones' location. Kim *et al.* found that there are no significant differences between the stone-free status and the location of the stone in the ureter (16).

One of the most important factors that condition the fragmentation and, consequently, the clearance of fragments, is the chemical composition of the stones. The concept of "stone fragility" was introduced by Dretler who found that the specific density of calcium oxalate monohydrate stones is 0.851 g/cm^2, for calcium oxalate dihydrate stones, 0.715 g/cm^2, whereas for uric acid it is 0.226 g/cm^2; further, he demonstrated that the most difficult fragmentation is found in patients with stones of calcium oxalate monohydrate and brushite, and the easiest fragmentation is found in stones made of uric acid and calcium oxalate dihydrate(17).

In this study, the analysis of the biochemical composition of stones was made by infrared spectroscopy in "Michel Daudon-Spectroscopy Center", "Dr. C. I. Parhon" Clinical Hospital, Iasi.

The vast majority of samples obtained by ESWL were of small size and the results implied only a global analysis (it was not possible to identify the specific composition of the core of the stone). We found that only 37.5% of the patients in whom the spectroscopic analysis showed the presence of COM were stone-free by ESWL. Except for this biochemical type of stone, the other crystalline species had stone-free rates of over 80%. It is noteworthy that there were no patients with brushite or cystine stones in this study. Our data on the poor performance of ESWL on the stones of COM differ from the data reported by Seitz, who found approximately similar fragmentation rates for both varieties of calcium oxalate (18).

In our study, 13.02% of the patients who underwent *in situ* ESWL did not have ureterohydronephrosis, and 92.3% of these patients were stone-free after the procedure, compared to 82.73% of those with grade II obstruction and 62% in the case of those with grade III ureterohydronephrosis. Similar studies on the influence of obstruction on the effectiveness of ESWL are contradictory. Thus, in a comparative study on the effectiveness of lithotripsy in patients with ureterohydronephrosis, Chang *et al.* find that the obstruction degree and the effectiveness of the procedure are directly correlated. Patients with high degrees of obstruction (III and IV) had significantly lower stone-free rates compared to patients with lower degrees of ureteral obstruction (19). The research of Kirkali *et al.* reveals that the ureteral obstruction is not a factor that negatively influences the disintegration of stones or the clearance of fragments resulting from extracorporeal lithotripsy. The two compared groups achieve similar stone-free rates, respectively 90% in the case of patients without obstruction and 85% in the case of those with ureterohydronephrosis (20). This hypothesis is also supported by the studies conducted by other authors who find that the presence of obstruction is not associated with a decrease in the stone-free rate, nor does it influence the number of pulses required to achieve fragmentation (19, 21).

Another factor with predictive value regarding the success of ESWL is represented by the presence of the ureteral stent. In a prospective randomized trial, Chandhoke *et al.* found that there are certain benefits of pre-ESWL ureteral stenting, especially the decrease in the number of colic episodes

and the number of post-procedural hospitalizations (22). Despite the benefits related to the prevention of complications, data available in the literature has demonstrated that the presence of JJ stents inserted before ESWL does not bring additional advantages. While some studies have demonstrated that ureteral stents do not influence the fragmentation rate (23, 24), most studies conducted on large groups of patients have demonstrated that the presence of ureteral stents correlates with lower rates of stone fragmentation and subsequent lower stone-free rates (25, 26, 27). The explanation is related, on the one hand, to the absence of the liquid interface between the calculus and the shock wave and on the other hand to the energy absorption by the stent (23, 28).

One of the most important limits of our study is the lack of computed tomography investigation of patients with ureteral lithiasis. It is demonstrated that the success of ESWL can be predicted by the determination of Hounsfield Units (HU). Thus, research dedicated to this topic has demonstrated that stones of sizes ranging between 10-20 mm and of densities higher than 1000 HU are associated with high probabilities of failure of ESWL (29). Joseph *et al.* demonstrated that the probability of fragmentation is inversely proportional to stone density: 55% for stones >1,000 HU, 86% for stones 500-1,000 HU and 100% for stones < 500 HU (30). The patients in our study were evaluated by KUB, which is a less reliable method to predict fragmentation. Krishnamurthy's results showed that patients in whom radiography revealed a calculus with a higher radiodensity than the one of the 12th rib, had a stone-free status of 60% (31). Also, we were not able to determine the skin-to-stone distance, which is an important predictor of the effectiveness of lithotripsy. Pareek *et al.* estimated that patients in whom this parameter exceeds 10 cm have the highest probability of treatment failure by ESWL (32). Our goal in the future is to evaluate these computer-tomographic parameters and correlate them with stone hardness and composition.

CONCLUSIONS

In situ extracorporeal lithotripsy is an efficient and safe method for the therapeutic management of patients with ureteral lithiasis, with better results if the procedure is performed as soon as possible after the onset of obstruction. In our study, we found that patients who had associated significant ureterohydronephrosis had lower stone-free rates after the procedure, compared to patients without ureteral obstruction. Regarding stone composition, patients with calcium oxalate monohydrate lithiasis had significantly lower stone-free rates in comparison to patients with stones made of calcium oxalate dihydrate, carbapatite or uric acid. We consider that the evaluation of stone density by computer tomography is necessary to assess the probability of fragmentation, but it cannot replace the morphological and spectroscopic analysis for the initiation of a targeted metaphylactic plan.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

ROLE OF THE PROSTHETIC MEDICAL DEVICES IN MANAGEMENT OF ABDOMINAL PARIETAL DEFECTS (Abstract): Management of abdominal parietal defects is a major public health concern, both nationally and internationally, due to morbidity, mortality, loss of function, decreased quality of life and loss of work capacity. **The aim** of this retrospective study is driven by the current possibility of treating abdominal parietal defects by prosthetic medical devices with various high-performance synthetic materials. **Material and methods:** The approach is from a statistical and multifactorial point of view in patients with abdominal parietal defects treated with prostheses in the I and II Surgery Clinics of "Sf. Spiridon" County Clinical Emergency Hospital Iaşi for a period of 15 years. The information was retrospectively obtained from the register of the hospital secretary and from the observation sheets, analyzing the cases on the basis of the multiple criteria. **Results:** The statistical analysis of the selected cases revealed that at a number of 5865 of abdominal wall defects surgeries that were performed in our clinics between 01.01.2006–01.07.2021 we recorded 3029 inguinal hernias (52%), 220 femoral hernias (4%), 796 umbilical hernias (13%) and 1820 incisional hernia (31%). The information on the main diagnosis associated with the 1820 subjects shows that most patients were hospitalized with the diagnosis of ventral hernia, 1122 cases without occlusion or gangrene (61.64%), 522 cases with obstruction (28.68%) and 176 cases with gangrene (9.6%). Obesity was the most common factor of risk for an abdominal wall defect with an index of 29%. The highest incidence of the develop of an incisional is reported on the midline, respectively 74%. **Conclusions:** Management of abdominal parietal defects is a major public health concern. Early diagnosis, easily accessible health facilities and health education are important to prevent complications and improve quality of life. **Keywords:** ABDOMINAL WALL DEFECTS; HERNIA; INCISIONAL HERNIA; PROSTHETIC MEDICAL DEVICES.

Management of abdominal parietal defects is a major public health concern, both nationally and internationally, due to morbidity, mortality, loss of function, decreased quality of life and loss of work capacity.

The first description of a hernia appears in the Ebers Papyrus in Egypt in 1550 BC.

There is evidence of hernia surgery since antiquity, with Hippocrates describing the umbilical hernia in 460-374 BC. This pathology is an ongoing concern, with the development of multiple surgical techniques over the years. The "modern" era of surgical treatment of hernia begins in 1958, when the procedure with polyethylene mesh (Marlex-50) was introduced by FC Usher, used in the case of inguinal hernias, and in 1984 Liechtenstein established the gold standard with the technique "tension-free", followed in 1992 by the development of laparoscopic techniques (1).

There is no universally valid definition of abdominal parietal defect, this may include recurrent or non-recurrent hernias, incisional hernias and eviscerations. A hernia is defined as the protrusion of a viscera, or anatomical tissue, through an existing or acquired orifice in the abdominal wall. Incisional hernia refers to abdominal wall hernia at the site of a previous surgical incision (2). Of the total interventions for the surgical treatment of parietal defects, in 60% of cases the prosthetic material used is mesh type and in 40% combined systems are used (3).

Incisional hernia develops in 11-20% of patients with laparotomy history, complicated with incarceration in 6-15% of cases and strangulation in approximately 2%. The recurrence rate after primary suture surgery is cited in approximately 54% of cases, up to 58% for tissue procedures and 20% for alloplastic procedures (4).

MATERIAL AND METHODS

The purpose of this retrospective study is driven by the current possibility of treating abdominal wall defects by prosthetic medical devices with various high-performance synthetic materials. The approach is from a statistical and multifactorial point of view of the parietal defects treated by prosthetic medical devices in the period 01.01.2006–01.07.2021, in the I and II Surgery Clinics of "Sf. Spiridon" County Clinical Emergency Hospital Iaşi.

The information was retrospectively obtained from the register of the hospital secretary and from the observation sheets, analyzing the cases on the basis of the following criteria:

- Age
- Sex
- Associated diseases
- Type of prosthetic medical devices
- Number of hospital days
- Immediate, remote, local, general complications

Regarding the analysis of cases with postoperative incisional hernia, the following criteria were also taken into account:

- The size of the parietal defect
- Number of previous incisions
- Type of initial incision.

The data systematized in this study was used in the analysis of the incidence of abdominal parietal defects in relation to the number of laparotomies performed in the two clinics, risk factors for the occurrence of the defect, recurrence and the occurrence of postoperative incisional hernia. These values should not be considered as an assessment of maximum accuracy, as it should be borne in mind that some patients come from outside the hospital area and others, with laparotomy events performed in the two clinics, may have turned to other surgical services. Another category of patients is represented by those patients with well-tolerated small abdominal parietal defect who did not request surgical consultation, remaining outside the evidence that was analyzed in this study. All data was collected in full acknowledgement of GDPR regulations and confidentiality, from hospital registry (5, 6).

Statistical analysis was performed as

case-control analyses, without adjustment for multiple testing, with nominal significance defined as $p<0.05$. Continuous variables were described using ANOVA test. The quantitative differences between the two groups were established with t-Student test. The categorial demographic data were compared using the Chi-2 test. The ROC curve (Receiver Operating Characteristics) helps us to measure the efficiency of a model, by drawing the specificity / sensitivity balance as a prognostic factor. The larger the area under the curve (the maximum is 1) the better the model.

RESULTS

The statistical analysis of the selected cases revealed that at a number of 5865 of abdominal wall defects surgeries that were performed in our clinics between 01.01.2006–01.07.2021 we recorded 3029 inguinal hernias (52%), 220 femoral hernias (4%), 796 umbilical hernias (13%) and 1820 incisional hernia (31%), (fig. 1).

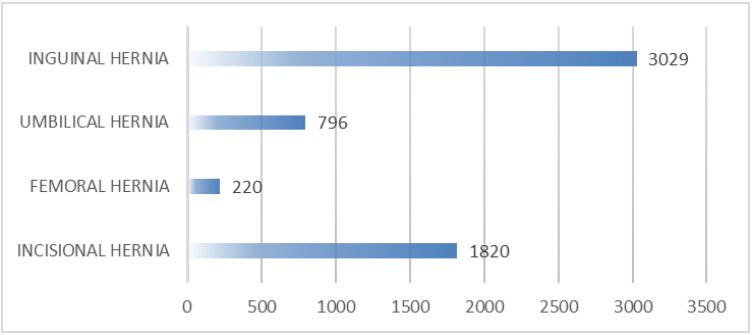

Fig. 1. This is a figure. Schemes follow the same formatting.

The data was analyzed in relation to the main local and systemic risk factors that interfere with the occurrence of the parietal defect.

Risk factors in the appearance of abdominal wall defects

• *Age and sex*

Patient gender data show the numerical difference between the sexes, which corresponds to a ratio of 2: 1 in favor of women in incisional hernia cases. This explained by the more frequent presence in females of risk factors conductive to postoperative parietal defects: decreased muscle tone after multiple pregnancies, obesity, weaker musculoskeletal layers, more frequent surgery on the lower abdomen as pelvic surgery, caesarean section, hysterectomies (tab. I).

TABLE I.

Incidence of inguinal hernias according to demographical data

	All groups N=5865	Incisional hernia N=1820	Other abdominal parietal defects N=4045	P values
Demographic data				
Age, mean±SD y (limits)	60.56±11.37 (17-98)	61.85±9.24 (30-96)	59.97±12.17 (17-98)	0.001*
Female, n(%)	2083 (35.5%)	1195 (65.7%)	888 (22.0%)	0.001**
≥ 60 years	3163 (53.9%)	1085 (59.6%)	2078 (51.4%)	0.001**

* t-student test ** chi2 test.

In inguinal hernia cases the main reason why men are more prone to inguinal hernias, both direct and indirect is due to reproductive anatomy and the inguinal canal in women is narrower., with a ratio of 8:1 (7.6:1) in favor of men. The umbilical hernia has a ratio of 1:1, and the femoral hernia has a ratio of 4:1 (3,6:1) in favor of women, because of the wider shape of the female pelvis (p=0.001) (fig. 2).

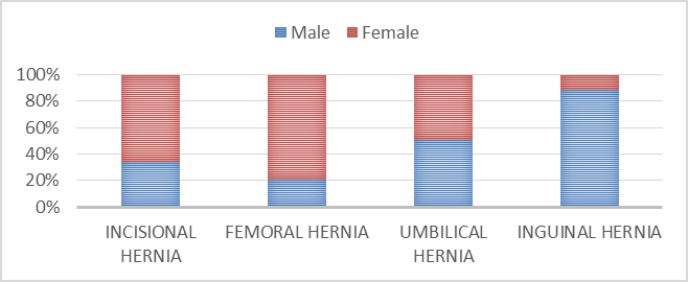

Fig. 2. Sex distribution by diagnosis.

The average age was highest in the group with femoral hernia and the lowest in the group with umbilical hernia (67.13 vs 57.97; p=0.001) (fig. 3).

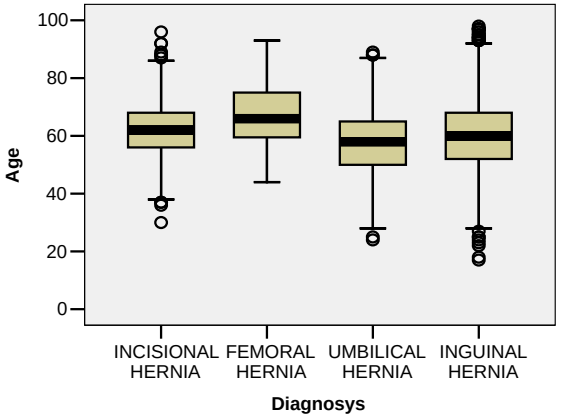

Fig. 3. Mean age by diagnosis.

Associated diseases

A hernia is often caused when there is a history of a hernia in the family. Straining your muscles due to intense weightlifting or coughing and even pregnancy may cause a hernia. When there is pressure on the abdominal area can lead to a hernia. Even issues like constipation, urinary obstruction along with chronic cough are risk factors. Obesity is also a major risk factor. As a hernia is caused when the tissue or part of muscle pushes out, damage to the elasticity and the strength of the tissue can also be a factor causing a hernia. Also, it may be due to residual embryological channels which is generally what a person is born with,

causing a congenital hernia.

Organic strains were found in a percentage of 62% being represented by various organo-systemic and metabolic disorders (fig. 4). Among the organic disfunctions mentioned, obesity was the most common with an index of 29%. Data on organo-systemic and metabolic disorders as individual risk factors provide an incomplete picture of their influence on the frequency of postoperative events. For a more rigorous interpretation it would be necessary to take into account their cumulative and synergistic effects.

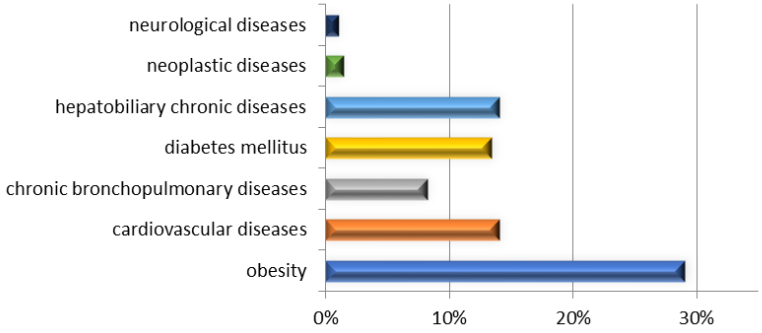

Fig. 4. Organo-systemic and metabolic disorders.

Obesity occurs more frequently under 60 years, muscle-aponeurotic structures begin to lose strength (table 2), chronic cardiovascular, lung disease and diabetes occur more frequently, and in women, the onset of menopause can trigger endocrine and metabolic disorders with a resounding decrease in the strength of supporting connective tissue (tab. III).

The repair of skin defects is incomplete and unfeasible in the elderly where epithelialization is delayed and limited, the vascular network recovers slowly and poorly, and the basement membranes recover abnormally. The scar tissue of the old man is younger compared to that of the body's original skin, the scar remaining immature for a long time.

TABLE II.

Organo-systemic and metabolic disorders by age group in patients with incisional hernia

Organo-systemic and metabolic disorders	< 60 years (n=625)	≥ 60 years (n=1195)	P values for Chi² test	OR	CI 95%
Obesity	369 (50.2%)	519 (47.8%)	0.321	1.06	0.95-1.18
Cardiovascular	359 (48.8%)	513 (47.3%)	0.513	1.04	0.93-1.16
Lung disease	228 (31.0%)	325 (30.0%)	0.628	1.03	0.91-1.16
Diabetes	340 (46.3%)	483 (44.5%)	0.464	1.04	0.93-1.17
Hepatobiliary	266 (36.3%)	402 (37.1%)	0.709	0.98	0.87-1.10
Neoplasic	126 (17.1%)	190 (17.5%)	0.838	0.99	0.85-1.14
Neurological	127 (17.3%)	192 (17.7%)	0.818	0.98	0.85-1.14

TABLE III.

Organo-systemic and metabolic disorders by sex in patients with incisional hernia

Organo-systemic and metabolic disorders	Female (n=1195)	Male (n=625)	P values for Chi² test	OR	CI 95%
Obesity	584 (48.9%)	304 (48.6%)	0.962	1.00	0.82-1.20
Cardiovascular	585 (49.0%)	287 (45.9%)	0.218	1.04	0.98-1.11
Lung disease	373 (31.2%)	180 (28.8%)	0.287	1.04	0.97-1.12
Diabetes	541 (45.3%)	282 (45.1%)	0.951	1.01	0.94-1.07
Hepatobiliary	441 (36.9%)	227 (36.3%)	0.806	1.01	0.94-1.08
Neoplasic	200 (16.7%)	116 (18.6%)	0.331	0.96	0.87-1.05
Neurological	203 (17.0%)	116 (18.6%)	0.404	0.96	0.88-1.05

The period of maturation and integration of the scar is double or even triple in duration in the elderly, and the resulting scar is worse than in the young, the evolution being able to be interrupted by lesions with secondary healing.

• *The influence of number of previous interventions in incisional hernia cases*

From a total of 1820 patients, 46.3% had previously undergone two or more surgeries on the abdominal wall for various conditions, all with at least one attempt at surgery to treat an incisional hernia by simple parietal suture and autoplastic methods or by prosthetic medical devices.

The number of surgeries performed on the abdominal wall recorded in the history of patients in the study group are shown below (fig. 5).

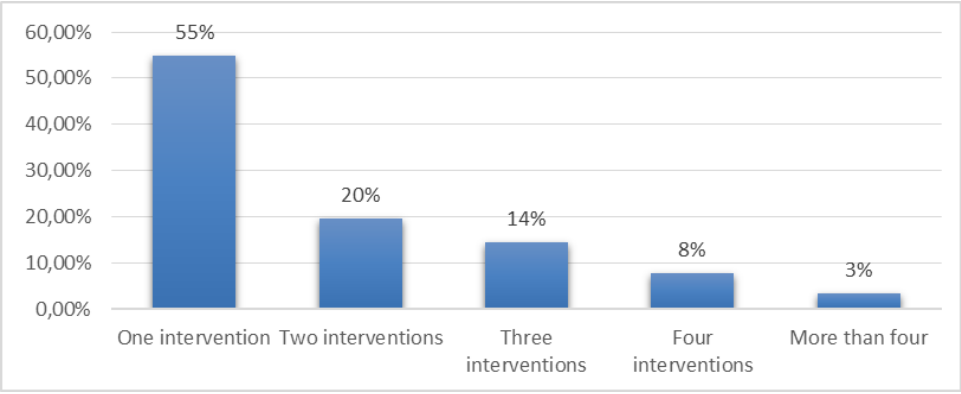

Fig. 5. Distribution of incisional hernia cases by history of previous surgeries.

• *Topography of the parietal defect*

The approach to resolving the condition of origin of the current parietal defect generally followed the place of establishment of the incisional hernia.

Some topographic regions predispose to parietal scarring defects either by the distribution of aponeurotic-fascial structures in the superficial planes and enduring a constantly positive intra-abdominal pressure (sub umbilical region), or by high tension in the scar caused by the presence

of close bone marks. However, the highest incidence is reported on the midline, respectively 74%. This is explained by the fact that the median laparotomy offers the best comfort in resolving surgical emergencies, being preferred by most surgeons. The topography of the parietal defect overlapped in most patients (~97%) with that of the last laparotomy performed.

The information on the main diagnosis associated with the 1,820 subjects shows that most patients were hospitalized with the diagnosis of ventral hernia, 1,122 cases without occlusion or gangrene (61.64%), 522 cases with obstruction (28.68%) and 176 cases with gangrene (9.6%).The appearance of the current event finds its explanation in a series of elements related to:

• Conditions in which the laparotomy (emergency or election) was performed.

• The lesions encountered and how to resolve them.

• Incidence of the infectious process and contamination or not of the parietal wound.

• Quality of parietal strength structures.

• Anesthetic conditions under which the operation was performed,

• Reaction to the suture material used (intolerance, granulomas).

The recurrence of the events poses problems of surgical resolution of the musculo-aponeurotic gap and difficulty in choosing the right method of restoring the wall to avoid a new recurrence. It, and especially the multi-recurrence, draws attention to the cumulation in the same patient of several local and general risk factors that must be taken into account when choosing the treatment method.

A new attempt to repair the wall by the same methods used previously without results is illusory and will further compromise the local anatomical structures.

Regarding recurrence, in just over half of the cases there were primary events (1,010 and 55.5%, respectively) and a number of 810 patients had multiple recurrent incisional hernia. In 18% of patients, it was intervened in the antecedents 2 or more times by classical methods of suturing the edges of the parietal defect.

• *The size of the parietal defect*

Another risk factor that may influence the therapeutic outcome is the size of the parietal defect (fig. 6).

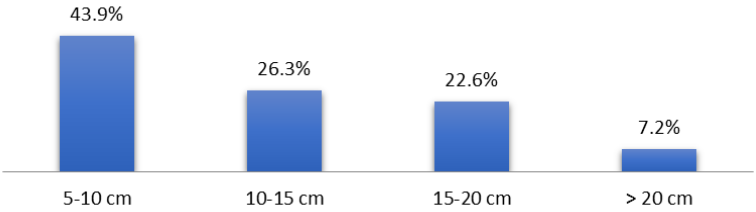

Fig. 6. Distribution of incisional hernias according to the size of the parietal defect.

About 7% of patients with incisional hernia were over 60 years old, female, and had complications (tab. IV).

ROC curve not confirmed age (AUC=0.479; IC95%: 0.453-0.506; p=0.131), gender (AUC=0.498; IC95%: 0.471-0.525; p=0.875) and presence of complications (AUC=0.494; IC95%: 0.468-0.521; p=0.685) as good predictors of a high size of parietal defect (fig. 7).

TABLE IV.
Size of parietal defect in relation with characteristics in patients with incisional hernia

Characteristics	Size of parietal defect				P value for Kruskal-Wallis test
	> 20 cm	15-20 cm	10-15 cm	5-10 cm	
Age ≥ 60 y	78 (7.2%)	261 (24.1%)	284 (26.2%)	462 (42.6%)	0.439
Female	83 (6.9%)	271 (22.7%)	317 (26.5%)	524 (43.8%)	0.898
Complicated	55 (7.5%)	159 (21.7%)	192 (26.2%)	328 (44.7%)	0.659

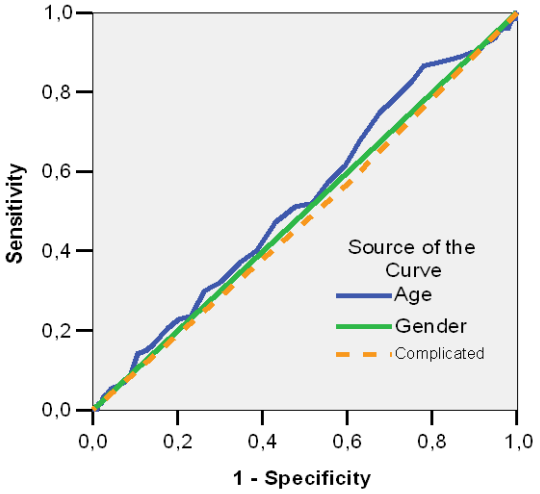

Fig. 7. ROC curve. Epidemiological data predictors of parietal defect size.

Prosthetic methods and techniques used

The chosen method depends mainly on the size of the parietal defect, but with the diversification of the available prosthetic materials, it became necessary to correlate the characteristics of the mesh with the technique of abdominal repair.

Polypropylene nets (PP) are the most widely used. It does not stimulate the immune response or rejection, being quickly incorporated by fibroblasts and granulation tissue that passes easily and fills the spaces between the nodes. Due to the low porosity, the chances of bacteria colonizing are low and the infections exceptional.

Multifilament polyester (PET) yarns are made of soft, fine, soft, durable and elastic nets. In addition, they can be adapted to all shapes and surfaces. The structure of the thread is responsible for the greater tissue inflammatory response than that of the propylene mesh.

In order to eliminate material incompatibilities, it is recommended that the non-absorbable nets (PP, PET) be sutured with non-absorbable threads, preferably from the same material from which the mesh is made.

The most commonly used composite mesh are the double layer: PP with Vicryl

type layer (resorbable copolymer based on glycolic acid and lactic acid) or with non-absorbable layer of e-PTFE (expanded polytetrafluoroethylene-expanded Teflon). Such nets have the advantage of weak adhesions that are established with the abdominal organs when they come in contact with them, but they are more expensive.

The treatment of events in the case of the patients in the analysis group was mainly based on polypropylene prosthetic materials several polyester mesh and more recently, composite mesh, implanted at different stratigraphic levels.

We treated 6 selected cases of incisional hernia by laparoscopic abord. The incisional hernia was positioned in 2 cases in the abdominal midline, 2 cases in the right inguinal fossa, and 2 cases in the umbilical region.

The patients were placed in the lithotomy position and then in the Trendelenburg position (30°). An open technique of creation of pneumoperitoneum was used, at a 12-14 mmHg intra-abdominal pressure. The vital signs (ECG, non-invasive blood pressure measurement, inspired O_2 concentration, tidal volume, airway pressure, pulse oximetry, capnography, temperature) were recorded during surgery, but there was no change in vital parameters after the abdomen was insufflated with carbon dioxide at this pressure. The video monitor placed on an instrument tower at eye level, on the right side of the patient, in front of the main surgeon. To facilitate instrument manipulation along with adequate visualization during laparoscopy, trocars usually are placed in triangular fashion termed triangulation, as far as possible from the site of expected adhesions. The 11 mm optical trocar was placed in the left hypochondrium, as far as possible laterally from the defect to provide clear visualization of the defect margins, and 3 other trocars (10 mm and 2 of 5 mm). Adhesiolysis was limited to the expected landing zone of the mesh on the peritoneal surface of the abdominal wall (fig. 8).

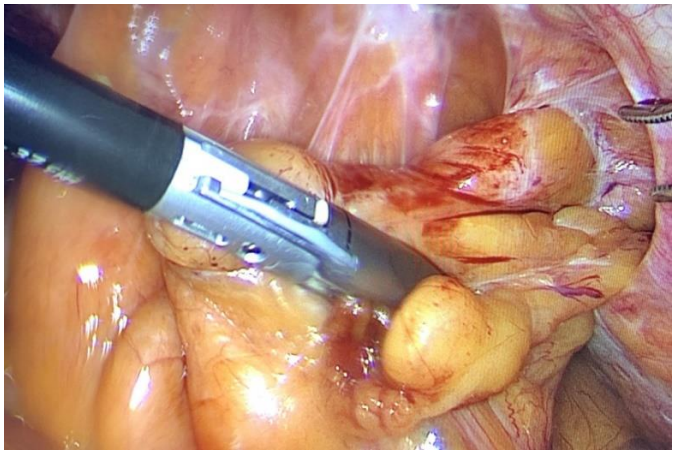

Fig. 8. Adhesiolysis of the incisional hernia.

We used polypropylene prosthetic medical device introduced in the abdomen through the 10-mm trocar site, avoiding contact with the skin. The omentum was used as a protective layer over the viscera in repair of the incisional hernias using on-lay technique.

Sutured was performed with an overlap of 3-5 cm of the borders by using a non-absorbable suture material trans-percutaneous in 4 patients, using a Reverdin needle (fig. 9A) and metallic tackers fixation in 2 patients placed at intervals of 1.5 cm (fig. 9B).

The interventions were uneventful, without devitalized or injured small intestine during de dissection of the incisional hernia sac.

B. Metallic tackers fixation of the prosthetic medical device.

Postoperative morbidity

Postoperative morbidity was divided into three evolutionary stages: (i) immediate morbidity (first 48 hours postoperatively); (ii) early morbidity (first 30 days postoperatively); (iii) late morbidity (more than 30 days after surgery).

- Immediate morbidity - the immediate postoperative course was simple in 1,743 patients (95.8%) and with general and local complications in 76 cases (4.2%).
- The general complications registered a percentage of 3.8% (N=3) being represented by:
- 32 postoperative respiratory failures in patients with known chronic bronchopulmonary disease, which required respiratory surveillance.

- 16 dynamic postoperative ileus remitted after medical treatment.
- 24 febrile ascents (38 ° C) in patients who subsequently had suppuration of the surgical wound.
- Early morbidity - overlaps, over time, with postoperative hospitalization- in the first 30 days after the operation, 1678 patients (92.2%) had a simple evolution, and 142 (7.8%) developed general and local complications.

The death occurred in 4 patients. However, the patients were with associated: severe sepsis, postoperative parietal hematoma, acute postoperative coronary syndrome, mechanical ventilation-associated tracheobronchitis, left carotid chronic ischemic stroke, right hemiplegia, atrial fibrillation, essential hypertension, acute renal failure and acute renal failure.

Local complications occurred in 64 (12.8%) patients. In most of them (N = 35; 7%) the mesh was implanted supra-aponeurotic, and the complications, which manifested themselves in the form of serous-hematic collections in the vicinity of the prosthetic medical device and wound infections, are as follows:

- 29 subcutaneous hematomas (1.6%);
- 40 subcutaneous seromas (2.2%);
- 58 infections of the surgical wound (3.2%).

The therapeutic conduct was simple, consisting of surgical drainage of blood collections through the surgical wound, evacuation of serous collections by repeated punctures and direct drainage of septic collections.

Late morbidity was assessed after 30 days postoperatively, taking into account the period 01.07.2011-01.11.2021. The observation sheets of 192 patients who returned for the application of the therapeutic conduct were also analyzed at the Clinic I and Clinic II Surgery of the "St. Spiridon" Hospital. It should be noted that the number of cases of late complications may be higher because it cannot be ruled out that some patients may have turned to other surgical services for possible complications, patients who could not enter the monitoring of this study.

Patients who presented during the period 01.07.2011-01.12.2020 presented for the following complications:

65 (3.6%) patients presented with chronic local suppurations.

149 (8.2%) patients experienced recurrence of the incisional hernia.

14 (0.8) patients with intestinal obstruction formed by adhesive flanges.

Of the late complications, 75 were operated on and 32 parietal suppurations were cured by simply draining the septic collection, followed by secondary suturing of the dehiscent wound. In 3 patients with recurrent eventration, surgery was contraindicated due to multiple organic stains.

The following interventions were performed:

- 12 intestinal obstructions resolved by lysis of the adhesions. The prosthetic graft being integrated in the abdominal wall, the suture of the wound edges was made in the subtotal plane, disregarding the existence of the in the wall.
- 15 chronic suppurations with intolerance to the synthetic material benefited from the total ablation of the prosthetic medical device placed supra-aponeurotic.
- one chronic suppuration benefited from the partial excision of the mounted above the aponeurotic tissue and the installation of a new preperitoneal prosthetic medical device (a la Rives) which in turn was not tolerated and also partially excised,

the wall being partly sutured.

- patients who had recurrence of the eventration benefited from a new prosthetic medical device with the fit of the preperitoneal or intraperitoneal prosthetic medical device, as the case may be.

Analyzing late complications depending on the stratigraphic level of medical device implantation, it can be seen that most of them appeared after the implantation of the prosthetic medical device above the aponeurosis. Thus, out of a number of 192 events that presented for late complications, 107 patients (55.7%) had the prosthetic medical device implanted above the aponeurosis, and the remaining ones had the net implanted in the deep planes of the wall.

The duration of postoperative hospitalization was on average 9.2 days and was influenced by the associated morbidity. Of the 1820 cases analyzed in only 9 patients, the postoperative hospitalization period exceeded 30 days.

The representation of the data on the number of hospitalization days of the patients in the analyzed group shows that the number of those who resumed their activity after the first 10 days after surgery is significantly higher than those who required longer hospitalizations.

The condition at discharge is an indication of the postoperative evolution and from the data recorded in the 1820 patients it can be seen that the percentage of surgically cured (96.6%) is an argument in favor of the alloplastic cure of postoperative events.

DISCUSSION

Hernia is a common condition with an incidence of 2-15% (7). The World Society of Emergency Surgery (WSES) broadly categorizes abdominal wall hernias into groin hernias and ventral hernias based on anatomical location. Groin hernias are located at the bottom half of the body and includes these types of hernias: indirect inguinal, direct inguinal, and femoral hernias. Ventral hernias encompass the other types of hernias which include umbilical, epigastric, Spigelian, lumbar, and incisional hernias (8).

In our study the statistical analysis of the selected cases revealed that at a number of 5865 of abdominal wall defects surgeries that were performed in our clinics between 01.01.2006–01.07.2021 we recorded 3249 groin hernias, 3029 inguinal hernias (93%), 220 femoral hernias (7%). A similar study that analyzed a total of 46,717 persons operated for a groin hernia found that 97% of all groin hernia repairs were inguinal hernias and 3% femoral hernias (9). Inguinal hernia is the most frequently diagnosed hernia and during their lifetime one third of males are diagnosed with an inguinal hernia. The age distribution is bimodal with the highest incidence in childhood and after 50 years of age (10). Referring to the incisional hernia we found that is more frequent in females, with a ratio of 2: 1 in favor of women. In a study performed of a total of 368 incisional hernias that been operated in the First Surgery Clinic, University Emergency Hospital Bucharest, female sex was predominant (81.25%) (11).

The distribution by decades of age reveals a higher incidence of events within the 5th and 6th decades of life. The age distribution is bimodal with the highest incidence in childhood and after 50 years of age (10).

Organic strains were found in a percentage of 62% being represented by various organo-systemic and metabolic disor-

ders Among the organic dysfunctions mentioned, obesity was the most common with an index of 29%. The literature also cites that obesity is the main cause on abdominal wall defects (12-16).

The highest incidence is reported on the midline, the influence of the topography of the parietal defect is explained by the fact that the median laparotomy offers the best comfort in resolving surgical emergencies, being preferred by most surgeons. A systematic literature search performed concluded that he risks of developing an incisional hernia after primary elective median laparotomy is reported in the literature as being between 5 and 20% (17).

Patients requiring emergent surgery for hernia vary widely in presentation and management, and the variation in timing of urgent surgery impacts surgical outcomes. The small percentage cases with gangrene (9.6% cases with gangrene) reveals the prompt urgent surgical intervention. The literature cites that delay in surgery for emergent hernias increased the odds of major morbidity but not mortality, patients presenting with hernia and an indication for urgent surgical intervention may benefit from an operation as soon as feasible (18).

Referring to the treatment, the evaluation of the benefits and harms of repair techniques in adults, specifically comparing closure with mesh versus without mesh, most authors decided that mesh repairs probably reduce the rate of hernia recurrence, and reduce visceral or neurovascular injuries, making mesh repair a common repair approach. Mesh repairs may result in a reduced length of hospital stay and time to return to activities of daily living. Non-mesh repair is less likely to cause seroma formation and has been favored in low-income countries due to low cost and reduced availability of mesh materials (19-23).

Controversy exists regarding the outcomes following ventral hernia repair with polypropylene (PP) or polyester (PET) mesh. Some studies suggest that mesh material does not affect recurrence or infection in ventral hernia repair and that surgery can be safely performed with both PP and PET mesh (24-27), other authors polyester mesh placed during ventral hernia repair results in acceptable infection rates, and no direct bowel complications or fistulas (28).

Although there was a trend toward more recurrence with suture repair in our study, this was not statistically significant. Mesh repair was associated with seromas (2.2%) and infections of the surgical wound (3.2%) but is not statistically different from other studies (29).

Analyzing late complications depending on the stratigraphic level of prosthetic medical device implantation, it can be seen that most of them appeared after the implantation of the prosthetic medical device above the aponeurosis. Meshes implanted intraperitoneally are known to cause adhesions potentially resulting in complications such as chronic pain, enterocutaneous fistula, or mesh infection. A study was performed on rats, on a model mimicking a clinical situation like hernia repair by intraperitoneally implanted meshes when mesh has contact with normal and with de-peritonealized intestine. The high adhesion scores of rats with local de-peritonealization compared with the low scores of animals with intact peritoneum indicate that the integrity of intestinal peritoneum is a decisive factor for adhesion formation (30). There is no single treatment modality to prevent adhesion formation after abdominal wall defect repaired with prosthetic materials (31-33).

CONCLUSIONS

Abdominal hernia is a common problem in the general population. Abdominal hernias are more common in men than women, there is an obvious relationship between obesity, history of abdominal surgery, history of abdominal trauma, family history and hernias. Early diagnosis, easily accessible health facilities and health education are important to prevent complications and improve quality of life.

Based on the currently evidence in midline closure after elective laparotomy in the small bites technique can be recommended to significantly reduce the rate of incisional hernia. The additional use of a prophylactic mesh in high-risk patients can significantly reduce the occurrence of incisional hernia.

Mesh repair has a small reduction in recurrence rates compared with suture repairs for primary ventral hernias, but an increased risk of seroma and infection of the surgical site was observed.

VILAZODONE ENHANCES THE ENDURANCE CAPACITY AND IMPROVES THE BIOLOGICAL CHANGES IN TREADMILL TEST IN RATS (Abstract): The **aim** of our study was the evaluation of the vilazodone (VLZ) influence on the endurance capacity and biological modifications in rats subjected to forced exercise. **Material and methods:** For the experiment, 24 white Wistar rats, were randomly assigned into four groups. The substances were administered orally, in a single daily dose, for 14 consecutive days: Group 1 (Negative control): distilled water 0.3 mL/100g body without effort; Group 2 (Positive control): distilled water 0.3 mL/100g body subjected to effort; Group 3 (Mg): 200 mg/kg body magnesium chloride; Group 4 (VLZ): 20 mg/kg body vilazodone. The rats motor behavior and the endurance capacity were evaluated using the treadmill test, and some blood parameters, estimating the stress influence were assessed: The investigation protocol was approved and implemented according to recommendations of the "Grigore T. Popa" University of Medicine and Pharmacy Iasi Committee for Research and Ethical Issues. **Results:** The administration of VLZ resulted in a prolongation in distance traveled, an increase in the number of touches the opposite end of belt and a diminution in the number of delivered shocks. Moreover, it decreased the blood levels of glucose and cortisol, and increased the serum values of b*rain derived neurotrophic factor*. The use of VLZ was accompanied by an intensification of anti-oxidant enzymes activity, respectively a decrease of the oxidative stress marker level in blood. Its effects were less intense, when compared to Mg. **Conclusions:** The treatment with VLZ improved the physical performances and the endurance capacity in this experimentally-induced stress model in rats. The use of this antidepressant drug recovered the biochemical changes and produced antioxidant effects in animals subjected to forced exercise in treadmill test. **Keywords:** VILAZODONE, TREADMILL TEST, RATS, STRESS, BDNF.

Currently, the most commonly prescribed therapy for affective disorders is based on active agents that block the reuptake or degradation of monoamines at

the synapse. The administration of such drugs is associated with a variable response and long period (weeks to months) between the onset of administration and the achievement of clinical results (1). Paradoxically, the neurochemical effects of typical antidepressants are measurable in the days immediately following treatment initiation (2). This discrepancy suggests that, in addition to increasing serotonin and/or noradrenaline levels, classical antidepressants seem to be involved in the modulation of other cellular pathways to achieve the therapeutic effect (3).

A new theory of antidepressant function suggests that selective serotonin reuptake inhibitors create a window for change by increasing brain plasticity and increasing the patient's susceptibility to factors in their environment (4-6). Classical antidepressants, such as selective serotonin reuptake inhibitors, selective noradrenaline reuptake inhibitors, and monoamine oxidase inhibitors, therapeutic agents that participate in the modulation of brain monoamine levels, have limited efficacy and a delayed therapeutic response of several weeks or months (2).

The relatively new antidepressant drug, vilazodone (VLZ) is an indolylalkylamine derivative with a dual mechanism of action consisting of partial 5-HT1A receptor agonist and selective serotonin reuptake inhibitory activity. It does not bind with high affinity to norepinephrine or dopamine reuptake sites (7-9). VLZ is used for the treatment of major depressive disorder in adult patients (10). It also, has been found to improve mental and somatic symptoms in generalized anxiety disorder (7). Due to its unique mechanism of action, VLZ has the following therapeutic benefits: faster onset, higher efficacy, and lower risks of adverse events compared to currently used antidepressants, especially lower sexual side effects (11).

The purpose of our experimental research was the evaluation of the VLZ influence on the endurance capacity and biological modifications in rats subjected to forced exercise.

MATERIAL AND METHODS

Substances

VLZ (≥98% HPLC, molecular weight 477.99 g/mol, catalogue code: SML1098), magnesium chloride (anhydrous, ≥98%, molecular weight 95.21 g/mol, catalogue code: M8266), saline solution (molecular weight 18.02 g/mol, catalogue code: 07-6061) were bought from Sigma-Adrich Chemical Co (Steinheim, Germany). Substances were dissolved in saline solution, prepared proximately before the administration.

Laboratory animals

White Wistar rats (weighting 200-250 g, 6 months), healthy, non-genetically modified, with equal repartition by sexes were procured from the National Medical-Military Institute "Cantacuzino" for Research and Development, Băneasa Resort, Bucharest, Romania through the biobase of the "Grigore T. Popa" University of Medicine and Pharmacy, Iasi, Romania. The rats were kept in standard laboratory conditions (with constant temperature of 21°C ± 2°C, relative humidity of 50-70% and alternating lighting regime (light/dark ratio = 12 hours/12 hours), with standard food pellets and water *ad libitum*.

Treadmill test

The animals were randomly assigned into 4 groups of 6 rats each, and treated orally (using an esogastric tube), in a single daily dose, for 14 consecutive days, according to the following protocol: Group 1 (Negative control): distilled water 0.3 mL/100 g body without effort; Group 2 (Positive control): distilled water 0.3 mL/100 g body subjected

to effort; Group 3 (Mg): 200 mg/kg body magnesium chloride; Group 4 (VLZ): 20 mg/kg body vilazodone. During the experiment, the normal behavior of the laboratory animals was observed, by monitoring the general condition, posture, spontaneous behavior, movements, orientation ability, hair appearance, breathing, the reaction to various stimuli. All behavioral disturbances, changes in posture or reactions to handling, abnormal movements, stereotypic behaviors (excessive grooming, repeated circular movements), and any other bizarre behavior (self-mutilation, walking backwards) were noticed. On the 14th day of the experiment, 15 minutes after the administration of the substances, the animals from the last three groups were subjected to treadmill test. Magnesium chloride (Mg) was considered a positive control substance, with known effects on this behavioral model in rats.

This experimental model is part of the group of classical behavioral tests, being used to evaluate the motor function of laboratory animals and their ability to endure sustained physical effort. The treadmill for testing laboratory animals is a device that forces them to run on a rotating belt at a constant speed, having the same operating principle, as the treadmill used by humans for to practice physical exercises (12). The device allows the application of additional electrical stimuli (with constant intensity from 0 to 2 mA, called - electric shocks). These shocks push the animal to continue traveling, when it tends to stop, or when it stumbles and falls on the moving (12, 13). For each experimentation session of 8 minutes, the following were monitored: total distance covered; the number of applied electric shocks, the time of application of the electric shocks; the length of time the animal resists until the application of the first electric impulse; the number of touches of the opposite end of the conveyor belt.

Laboratory investigations

To compare the influence on the on the biological constants, we used the negative control group with rats not subjected to physical exercise. The blood samples (0.3 mL) were collected from the lateral tail vein after performing the exercise test (13). For the laboratory investigations the appropriate analyzers and kits to measure the blood level of glucose (Hematology Analyzer 5 DIFF model BF-5180, DIRUI, Istanbul, Turkey), cortisol (by electrochemiluminescence immunochemical method), and b*rain derived neurotrophic factor* (*BDNF*) (by ELISA method – using a specific kit) (15). The oxidative stress was evaluated (using a Shimadzu 1800 spectrophotometer, Kyoto, Japan, using the specific RANSOD kit from RANDOX Laboratories Ltd., Warsaw, Poland) by estimating the activity of: malondialdehyde - MDA (using the thiobarbituric acid method); glutathione peroxidase - GPx (using the dithio-nitrobenzoic acid method). The blood levels of superoxide dismutase - SOD, were assessed according to a method based on inhibiting the reduction of nitro blue tetrazolium with xanthine-xanthine oxidase, used as a superoxide generator.

The obtained results were expressed as arithmetic mean ± the standard deviation (S.D.) of the mean values and statistically analyzed using *SPSS* software for Windows EXCEL program (New York, Unites States) and ANOVA method. The *p* (probability) coefficient values lower than 0.05 were considered statistically significant compared to the control group.

The experimental studies were carried out after approval by the Ethics Committee of the University (Certificate No. 25/14.07.2020), in strict accordance with the international ethical regulations regarding work on laboratory

animals. The research methodology was established in accordance with international and national standards (16).

RESULTS

The treatment with Mg was linked to an increase in distance run (146.17±8.26 meters), statistically significant (**p <0.01) compared to distilled water group subjected to effort (107.17±8.16 meters). The administration of VLZ was accompanied by a substantial (*p <0.05) prolongation in distance traveled (124.83±3.49 meters) when compared to control group, but a little shorter than the one traveled by Mg group, the same time interval in treadmill test (fig. 1a).

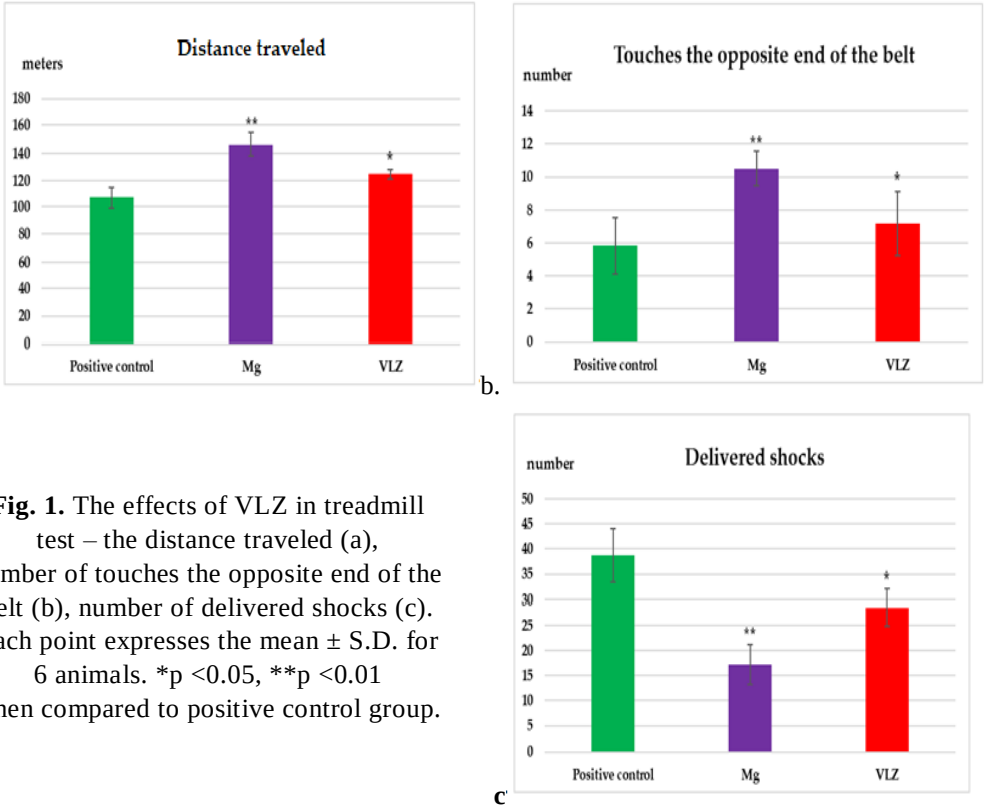

Fig. 1. The effects of VLZ in treadmill test – the distance traveled (a), number of touches the opposite end of the belt (b), number of delivered shocks (c). Each point expresses the mean ± S.D. for 6 animals. *p <0.05, **p <0.01 when compared to positive control group.

The treatment with Mg was correlated with a considerable (**p <0.01) increase in the number of touches the opposite end of the belt (4.83±1.72), compared to positive control animals (10.5±1.05). Oral administration of VLZ for 14 days led to an important (*p <0.05) increase in the number of touches (7.17±1.94) when compared to control group, but its effects were less intense than those of Mg group, the similar session in treadmill test (fig. 1b).

The administration of Mg was associated by a noticeable (**p <0.01) reduction in the number of delivered electric impulses (17.17±4.02), when compared to animals from distilled water group (38.83±5.31). The treatment with VLZ for 2 weeks resulted in an obvious (*p <0.05) decrease in

the number of needed shocks (28.50±3.62) comparing with positive control group, but, lower than those counted for Mg group, the same training session in forced exercise test (fig. 1c).

The use of Mg considerable (**p <0.01) increased the time need to first shock delivery (221 ± 8.65), and markedly shorten the time of providing electric stimuli (17.67 ± 2.80), comparing with positive control (134.33 ± 12.48, respectively 38.17 ± 4.17). The subacute administration of VLZ for 14 days caused an important (*p <0.05) prolongation of the time need to first shock use (184.67 ± 7.66), and a reduction in the time of providing shocks (31.17 ± 4.71), when compared to positive control (134.33 ± 12.48, respectively 38.17 ± 4.17) (tab. I).

TABLE I.

The effects of VLZ in treadmill test – time to first shock delivery, time of providing shocks (seconds). Each point expresses the mean ± S.D. for 6 animals. *p <0.05, **p <0.01 when compared to positive control group.

Groups	Time to first shock delivery	Time of providing shocks
Positive control	134.33 ± 12.48	38.17 ± 4.17
Mg	221 ± 8.65**	17.67 ± 2.80**
VLZ	184.67 ± 7.66*	31.17 ± 4.71*

TABLE II.

The effects of VLZ on blood levels of glucose, cortisol and BDNF in treadmill test in rats. Each point expresses the mean ± S.D. for 6 animals. *p <0.05, **p <0.01 when compared to positive control group, ♦p <0.05, ♦♦p <0.01 versus negative control group.

Groups	Glucose (mg/dL)	Cortisol (pg/mL)	BDNF (pg/mL)
Negative control	88.50 ± 6.24	0.14 ± 0.01	575.67 ± 47.25
Positive control	116.33 ± 1.53♦♦	0.19 ± 0.02♦	477.50 ±33.23♦♦
Mg	93.33 ± 8.02*	0.16 ±0.03	569.50 ±31.82*
VLZ	94.33 ± 3.06*	0.16 ±0.01	560.67 ±12.10*

An increase in blood glucose values was highlighted in the positive control group (116.33±1.53 mg/dL), statistically significant (♦♦p <0.01) compared to the negative control animals (88.50±6.24 mg/dL). The treatment with Mg for 14 days was associated with a significant reduction (*p <0.05) of blood glucose (93.33±8.02 mg/dL) compared to distilled water group subjected to exercise. The use of VLZ produced the relevant decrease (*p <0.05) in blood glucose level (94.33±3.06 mg/dL) compared to positive control, but less intense than noted for Mg group. In rats subjected to exercise stress, a significant increase (♦p <0.05) of the serum cortisol level (0.19±0.02 pg/mL) compared to animals without exercise (0.14±0.01 pg/mL) was detected. Mg caused a slight decrease in the cortisol level (0.16 ± 0.03 pg/mL), but without significance compared to positive control animals. The administration of VLZ led in a slight decrease in the blood value of cortisol (0.16±0.01 pg/mL), non-significant when compared to the positive control group (tab. II). The physical exercise induced a substantial de-

crease (♦♦p <0.01) in blood levels of BDNF (477.50±33.23 pg/mL), compared to the negative control group (575.67±47.25 pg/mL). The administration of Mg determined a relevant increase (**p <0.01) in the value of BDNF in the blood (569.50 ± 31.82 pg/mL), compared to distilled water group subjected to exercise. VLZ use led to an increase in serum BDNF (560.67±12.10 pg/mL), statistically significant (**p <0.01) compared to the positive control group, but weaker than produced by Mg (tab. II).

TABLE III.

The effects of VLZ on the SOD, MDA and GPx activity in treadmill test in rats. Each point expresses the mean ± S.D. of mean, for 6 animals in a group. *p <0.05, **p <0.01 when compared to positive control group, ♦p <0.05, ♦♦p <0.01 versus negative control group.

Groups	SOD (µg/mL)	MDA (nmol/L)	GPx (pg/mL)
Negative control	24.33 ± 2.46	27.83 ± 3.16	321.17 ± 33.27
Positive control	15.00 ± 2.83♦♦	38.50 ± 2.40♦♦	194.00 ± 35.36♦♦
Mg	23.00 ± 1.41*	26.65 ± 3.46**	311.50 ±113.84**
VLZ	20.83 ± 3.37*	29.57 ± 3.54*	307.67 ± 75.65**

A significant (♦♦p <0.01) decrease in SOD activity (15.00±2.83 µg/mL) compared to the negative control group (24.33 ± 2.46 µg/mL) was revealed in positive control animals in the treadmill test. The use of Mg was correlated with an obvious enhancement (*p <0.05) of SOD activity (23.00±1.41 µg/mL), compared to positive control group. The administration of VLZ was followed by marked intensification (*p <0.05) of SOD activity (20.83±3.37 µg/mL), when compared to the positive control group, but with less importance that observed for Mg group (tab. III). The positive control animals showed a considerable increase (♦♦p <0.01) of MDA activity (38.5±2.40 nmol/L), compared to the negative control (27.83 ± 3.16 nmol/L). The treatment with Mg induced an obvious diminution (**p <0.01) in the serum values of MDA (26.65±3.46 nmol/L), comparing with distilled water group with effort. The use of VLZ was accompanied by a notable (*p <0.05) decrease in the blood level of MDA (29.57 ± 3.54 nmol/L), compared to positive control group (tab. III). Subjecting control rats to physical exercise resulted in an obvious decrease (♦♦p <0.01) of GPx values (194.00 35.36 pg/mL), compared to the negative control animals (321.17±33.27 pg/mL) (Table 3). Mg caused a significant increase (**p <0.01) in the serum level of GPx (311.50±113.84 pg/mL), compared to distilled water group subjected to exercise (Table 3). The treatment with VLZ resulted in the increase of GPx values in blood (307.67±75.65 pg/mL), with statistical significance (**p <0.01) compared to positive control animals (tab. 3).

DISCUSSION

The administration of VLZ, during 14 consecutive days was associated by an increase in endurance capacity to forced exercise, objectified by the prolongation the distance traveled by the animal on the treadmill, the increasing in the number of touches the opposite end of belt, and a decreasing in the number of delivered electric stimuli. Biochemical analysis showed

that the treatment with VLZ significantly improved the glycaemia and decreased the serum value of cortisol. The effects of this antidepressant drug on these two parameters were of lower intensity than those induced by Mg in rats.

We investigated the modification of BDNF blood values in rats subjected to forced exercise, and the influence of the administration of VLZ. In our experimental condition the use of VLZ was followed by a substantial increase in the serum level of BDNF, *thus suggest its obvious stress-reducing effects in rats exposed to physical effort. Its effects were less intense when compared to Mg.* BDNF plays a critical role in the development of mental illnesses such as depression and anxiety (17). Previous research has also demonstrated the relationship between stress and BDNF expression in many critical brain regions (18). Clinical studies report that serum BDNF levels are decreased in depressed patients and then increased in response to treatment with typical antidepressants. Reduced BDNF is also observed in post-mortem tissue of untreated depressed individuals (19). Physical activity has been shown to increase BDNF mRNA expression in multiple brain regions, especially in the hippocampus, which is consistent with the delay in the antidepressant behavioral response in experimental rodent models (20). Recent studies have highlighted the fact that the induction of BDNF expression in the hippocampus is important in the manifestation of the effectiveness of antidepressant treatment, and its repression seems to have a determining role in the pathophysiological mechanisms of depression, in various animal models (21). Conversely, sustained induction of BDNF in the nucleus accumbens, which persists for at least one month after chronic stress, mediates depression-like behavioral abnormalities, while reversal of this effect induces an antidepressant response (22-24).

In response to endurance training in rats, free radicals are generated due to oxidative stress. The assessing of blood levels of MDA, GPx and SOD offers the possibility of estimation of VLZ influence on the cellular oxidative processes. In animals exposed to forced exercise training high levels of MDA in blood, as well as a diminution in SOD and GPx activity was detected. The improvement of the changes observed in these parameters, following the use of VLZ, suggests its influence of reducing oxidative stress. *The use of VLZ was accompanied by an intensification of antioxidant enzymes activity, respectively a reduction of the serum value of* MDA. *Its effects were less intense, when compared to magnesium.*

CONCLUSIONS

The treatment with VLZ improved the physical performances and the endurance capacity in this experimentally-induced stress model in rats. *The use of this antidepressant drug recovered the biochemical changes and produced antioxidant effects in animals subjected to forced exercise in treadmill test.*

CONFLICT OF INTEREST

The authors declare that there is no conflict of interest.

THE PROINFLAMMATORY ROLE OF SERUM IL-6 IN ACUTE OTITIS MEDIA IN CHILDREN (Abstract): Acute otitis media (AOM) represents the leading cause of health care visits and antibiotic prescriptions in children. In order to reduce the unnecessary antibiotic prescriptions and to avoid the burden of potential complications, new biomarkers may be useful for the diagnosis and follow-up of children with AOM. **Material and methods**: We performed a prospective study in pediatric patients with AOM hospitalized in a tertiary hospital in Iasi, Romania, during a 1-year period (between November 2021 and November 2022). We assessed the utility of serum interleukin-6, S100A12 protein, ESR (erythrocyte sedimentation rate) and CRP (C-reactive protein) in the diagnosis of children with clinical signs of AOM. **Results**: A total of 88 children, aged between 2 months old to 17 years old were included (46 with AOM and 42 healthy controls). The differences between the control group and AOM group were statistically significant ($p<0.001$) for ESR, CRP and IL-6 (median values being much higher in the case of patients with AOM). The differences between the control group and the one with AOM were only random ($p=0.326 > 0.05$) in case of S100A12 protein. ESR > 27 mm/hour was associated with a 2 times higher risk (RR=2.022) of having concomitant adenoiditis. **Conclusions**: IL-6 could offer a powerful tool for the objective evaluation of AOM. Further research is needed to fully elucidate the role of IL-6 in AOM and to determine whether it may be a useful biomarker for predicting treatment outcomes. **Keywords**: ACUTE OTITIS MEDIA, CHILDREN, IL-6, S100A12 PROTEIN.

Acute otitis media (AOM) is defined by the American Academy of Pediatrics as the rapid onset of signs and symptoms of inflammation in the middle ear, with or without otorrhea (1). In children, AOM represents an important healthcare issue due to high rates of antibiotherapy (2). Despite overall reduction in the incidence of AOM after the introduction of pneumococcal conjugate vaccines, Hu *et al.* reported at least one episode of AOM in 28.6% to 31.5% of the children younger than 2 years old in 2022 (3). In the United States, about 60% of children experience an episode of AOM before the age of 3 (4). In this context, AOM still represents the leading cause of health care visits and antibiotic prescriptions (5), with additional burden arising

from long-term complications, as hearing loss that impacts language acquisition and educational outcomes (6).

Currently, the diagnosis of AOM is based on signs of inflammation on otoscopy combined with clinical history and presenting signs and symptoms (7). As these methods may have a certain grade of subjectivity derived from the healthcare professional, but also from the perception of the parents on the pain and discomfort of their child, a more objective approach may be welcome. Microbiological culture and antibiotic sensitivity testing is useful in order to justify the antibiotic prescription, but the available guidelines do not routinely recommend performing a tympanocentesis (8). Also, blood tests (complete blood count, acute phase reactants such as C-reactive protein, erythrocyte sedimentation rate and fibrinogen, cultures) are performed only under specific circumstances (recurrent AOM, complications or treatment failure, follow-up) (9).

Recent discoveries emphasized the potential role of cytokines, a group of glycoproteins, in the modulation of inflammatory and immune reactions in AOM. Interleukin-6 (IL-6), an inflammatory mediator with pleiotropic effects, is highly produced during the initial stage of inflammation (10). Higher levels of serum IL-6 were found at the moment of diagnosis in children with AOM due to *Streptococcus pneumoniae*, but these results are difficult to extrapolate to other populations as the study sample comprised only 12 children (11). A less-studied molecule in the context of inflammation associated to AOM is S100A12 protein, also known as calgranulin C. Markedly overexpressed levels of S100A12 protein have been reported in inflammatory compartments, but the potential usefulness in clinical practice in the context of AOM has not yet fully established (12).

In order to reduce the unnecessary antibiotic prescriptions and to avoid the burden of potential serious complications, new biomarkers may be useful for the diagnosis and follow-up of children with AOM. Our aim was to assess the utility of serum interleukin-6 and S100A12 protein in the diagnosis of children with clinical signs of AOM.

MATERIAL AND METHODS

We performed a prospective study in pediatric patients with AOM hospitalized in "Sf. Maria" Emergency Hospital for Children, a tertiary hospital in Iasi, Romania, during a 1-year period (between November 2021 and November 2022). The study protocol was reviewed and approved by the Ethical Committees of "Grigore T. Popa" University of Medicine and Pharmacy, Iasi, Romania (No. 12292-22.07.2020) and of "Sf. Maria" Clinical Emergency Hospital for Children, Iasi (No. 34306/ November 5, 2020). Written informed consent was obtained from the parents of all study participants.

We included the children aged 0-18 years old who were diagnosed with AOM in the ENT Department based on the following criteria: acute onset of the symptoms (fever, irritability, otalgia or otorrhea) and at least 2 signs of middle ear effusion confirmed by otoscopy (bulging or erythema of the tympanic membrane, air-fluid level behind the tympanic membrane, limited or absent mobility of tympanic membrane). Only children with a recent onset of AOM symptoms (the first 48 hours) who did not receive any antibiotic treatment were considered for our analysis. Patients with acute comorbidities which might have triggered a more powerful inflammatory

response - e.g., lower respiratory tract infections, gastroenteritis, urinary tract infections, meningitis or with chronic systemic conditions - e.g., diabetes mellitus, cancers or autoimmune disorders were excluded from our sample. We also set up a control group with children who presented in our hospital for a routine check-up, with no current infection or inflammatory disease.

At hospital admission, 3 mL blood samples were obtained from both AOM and control groups and collected in heparin-free tubes at room temperature. After centrifugation at 2000 x g for 15 minutes at 4 °C, we obtained serum samples which were immediately stored at – 80 °C. The Enzyme-Linked ImmunoSorbent Assay (ELISA) method was used to measure the IL-6 (code E-EL-H0102 ELISA Kit) and S100A12 protein (code E-EL-H1293 ELISA Kit) levels. Both kits were provided by Elabscience, United States of America. The micro-ELISA plate has been pre-coated with an antibody specific to Human IL-6 and Human S100A12, respectively. The samples were added to the micro-ELISA plate wells and combined with the specific antibody using the Sandwich-ELISA principle. Then, a biotinylated detection antibody specific for Human IL-6 and Human S100A12, respectively with an Avidin-Horseradish Peroxidase (HRP) conjugate were added successively to each micro plate well and incubated. Free components were washed away, and the substrate solution was added to each well. The enzyme-substrate reaction was terminated by the addition of stop solution which turned the color into yellow. The optical density (OD) was measured spectrophotometrically at a wavelength of 450 nm ± 2 nm. As the OD value was proportional to the concentration of IL-6 and S100A12 protein, respectively, we calculated these concentrations in the samples by comparing the OD of the samples to the standard curve.

Besides demographic data (age, gender), we also recorded data regarding significant commorbidies (adenoiditis), the hospitalization length, the potential complications and the readmissions to hospital in the following 5 months. We have also analyzed biologic markers - C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) in both AOM and control group. The normal range provided by the laboratory of our hospital is less than 5 mg/L for CRP and less than 12 mm/hour for ESR.

Data obtained were analyzed using specific statistical functions provided by SPSS software, as the non-parametric Mann-Whitney U test, as well as Spearman's rank correlation coefficient. P values < 0.05 were considered statistically significant.

RESULTS

A total of 88 children aged between 2 months old to 17 years old were included in our analysis, among which 46 were diagnosed with AOM and 42 were healthy controls presented to our hospital for a routine check-up. The descriptive statistics revealed significantly higher values for ESR, CRP and IL-6 in children with AOM than in controls (tab. I). The distributions of the ESR, CRP, IL-6 and S100A12 protein in controls and cases are represented in first figure.

Our data were not normally distributed, and therefore, instead of using the t-test for comparing independent samples, we needed a non-parametric alternative test, which in this case was the Mann-Whitney U Test (tab. II), which does not require the assumptions of normality of variables and homogeneity of variances. The test showed that the differences between the control

group and AOM group are statistically significant ($p<0.001$) for ESR, CRP and IL-6 (median values being much higher in the case of patients with AOM, which is also illustrated in fig. 1). The values of the Rank-Biserial Correlation indicator showed an important effect of these differences between the control group and the otitis group for ESR, CRP and IL-6, their magnitude being above the threshold of 0.50. The differences between the control group and the one with AOM were only random ($p=0.326 > 0.05$) in case of S100A12 protein.

TABLE I.

Descriptive statistics of the main parameters analyzed in AOM cases and healthy controls

	ESR (mm/h)		CRP (mg/dL)		IL-6 (pg/mL)		S100A12 protein (pg/mL)

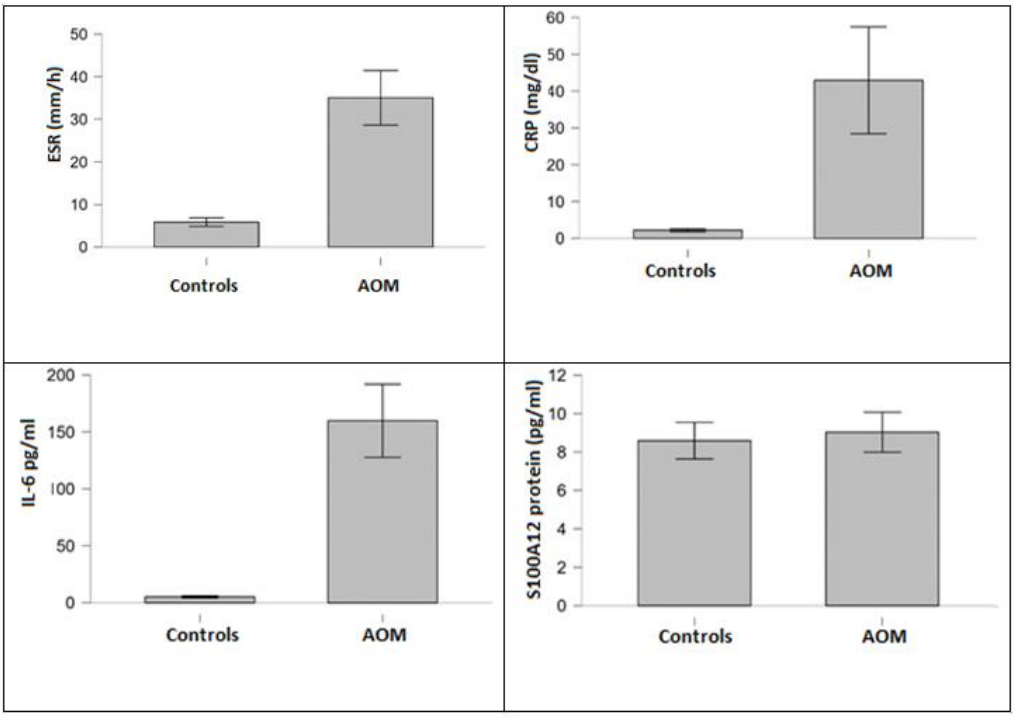

Fig. 2. Distribution of the ESR, CRP, IL-6 and S100A12 protein in controls and cases

As the assumption of normality of the sample was previously violated (the Shapiro-Wilk test registers statistically significant values in all situations, respectively $p < 0.05$), we used Spearman's correlation coefficient instead of Pearson's coefficient to highlight the existing correlations between ESR, CRP, IL- 6 and S100A12 (tab. III). A matrix of correlation coefficients between the 4 variables, which also contains the level of statistical significance associated with each variable was generated (tab. III). A strong direct (positive) relation between CRP and ESR ($rs = 0.630$, $p < 0.001$) and a direct link of medium intensity between IL-6 and ESR ($rs = 0.3090$, $p < 0.05$) were observed. No statistically significant correlation was revealed between the other pairs of variables.

The association between the presence of adenoiditis and the value of ESR > 27 mm/hr was statistically significant ($\chi^2=5.841$, $p<0.05$). Moreover, an ESR > 27 mm/hr was associated with a 2 times higher risk (RR=2.022) of having concomitant adenoiditis (fig. 2).

Table II.

Mann-Whitney U test

	W df	p	Hodges-Lehmann Estimate	Rank-Biserial Correlation	SE Rank-Biserial Correlation
ESR	9.000	**< .001**	-22.000	-0.991	0.123
CRP	37.000	< .001	-11.840	-0.962	0.123
IL-6	0.000	< .001	-114.324	-1.000	0.123
S100A12	848.000	0.326	-0.650	-0.122	0.123
Note. For the Mann-Whitney test, effect size is given by the rank biserial correlation.

S100A12 protein	Spearman's rho	0.195	0.185	0.229	—
	p-value	0.193	0.219	0.125	—

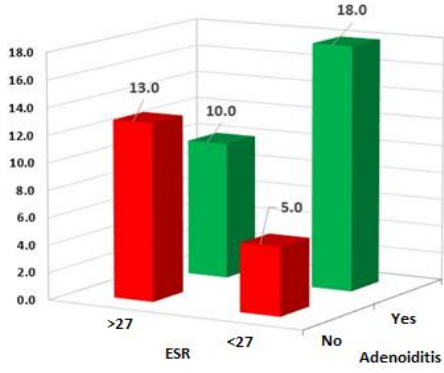

Fig. 2. Correlations between adenoiditis and ESR>27 mm/h

No statistical significance was found between adenoiditis and CRP > 50 mg/L (χ^2=2.741, p=0.098) or between bilateral AOM and CRP > 50 mg/L (χ^2=0.063, p=0.801).

The average hospitalization length was 5 days and no serious complications or readmissions to hospital have occurred in the following 5 months in the AOM group.

DISCUSSION

The role of IL-6 in the diagnosis of AOM

IL-6 is a pleiotropic cytokine, commonly referred as a primary mediator of the acute phase response, which plays an important role in the inflammatory reaction to bacterial infections (13). Up to the present, its important role in inflammation, innate and adaptative immune responses has been recognized in various studies (14, 15). During the resolution phase of the infections, IL-6 promotes the reduction of the neutrophil infiltrate and initiates an acquired immune response (16). In contrast to other cytokines, the production of IL-6 may continue even after the initial stimulus has been removed, being eliminated in a lower rate than other cytokines (17). This may explain why higher levels of IL-6 were found in the sera from patients with AOM in the early phases of the disease in comparison with healthy controls.

Several studies have investigated the role of IL-6 in AOM in children, but the exact role of IL-6 in the pathogenesis of AOM has not been clearly established yet. However, it was almost 35 years ago when Heikkinen *et al.* already reported that low levels of IL-6 cannot solely exclude the bacterial etiology of acute otitis media (18). Our results regarding IL-6 serum levels are in accordance with those of Scharer *et al.*, who found higher mean concentrations of IL-6 in a sample of 10 children with AOM compared to healthy controls (p = 0.05) (11). Also, our findings were consistent with another study performed in a sample of 14 children with AOM (19). However, these results are difficult to interpret and extrapolate as in pediatrics, there are often difficulties in developing studies on larger samples.

The optimal cut-off value for serum IL-6 to discriminate AOM from healthy controls has yet to be clearly established. However, the role of IL-6 has been better described in chronic otitis media. For instance, in a study comparing the role of interleukin 1α (IL-1α), IL-6 and interleukin 8 (IL-8) in the chronic evolution of otitis media, Serban *et al.* reported that IL-6 serum values recorded the highest mean level in chronic suppurative otitis media ranging from 57.23 to 193.33 pg/mL (20). In our sample, the serum IL-6 levels ranged from 44 to 443.3 pg/mL, with a medium level of 118.815 pg/mL, which might suggest that higher levels of IL-6 can be correlated to acute rather than chronic otitis media. It has been shown that IL-6 levels also decrease after antibiotic treatment, suggesting that IL-6 is involved in the response to bacterial infection (11).

In vitro studies have shown that IL-6 is produced by middle ear epithelial cells and fibroblasts in response to bacterial components, such as lipopolysaccharides (LPS), and that IL-6 production is enhanced by other cytokines, such as TNF-α and IL-1 β. IL-6 can also stimulate the production of other cytokines, such as IL-8, which promote neutrophil recruitment and activation in the middle ear (21). The role of IL-6 in AOM has been also investigated in animal models, such as mice and chinchillas. In these models, IL-6 levels were found to be elevated in the middle ear after bacterial

inoculation, and IL-6 blockade with antibodies or genetic deletion resulted in reduced neutrophil recruitment and less severe middle ear inflammation (22). IL-6 has also been investigated as a potential therapeutic target in AOM. Blockade of IL-6 signaling has been shown to reduce middle ear inflammation and improve clinical symptoms in animal models (23).

S100A12 protein in the diagnosis of AOM

Firstly, described in 1995 by Guinard *et al.* (24), S100 calcium-binding protein A12 (S100A12 protein), also known as calgranulin C, MRP6, or EN-RAGE (extracellular newly identified receptor for Advanced glycation end products binding protein), belongs to the S100 family of low molecular weight proteins (25). S100A12 protein is predominantly localized in the cytoplasm of myeloid cells such as neutrophils (26), but recent data suggest that, under inflammatory conditions, it can also be present in epithelial and endothelial cells and in pro-inflammatory macrophages (27). Besides its role in calcium homeostasis, S100A12 protein express chemo-attractive properties to immune cells, leading to a pro-inflammation state via TLR-4 and RAGE pathways (28). Recent data reveals the role of S100A12 protein in the evaluation and assessment of several inflammatory disorders, including Behçet's disease (29), familial Mediterranean fever (30), Kawasaki's disease (31), inflammatory bowel disease (32) and AOM (33).

Several studies depicted its antimicrobial role, mainly via a nutritional immunity – based mechanism, as essential transition metals for the growth and resistance of the microorganisms are depleted during the infections. For instance, S100A12 protein exerts inhibitory activity against *Campylobacter jejuni* (34) and *Helicobacter pylori* through a zinc+-dependent sequestration (35). Moreover, S100A12 expresses antiparasitic properties, by enhancing the production of superoxide possibly through the binding of copper (36).

Contrary to our results, higher levels of S100A12 protein were reported in children with AOM than in healthy controls. According to Liu *et al.*, increased serum levels of S100A12 protein were found at the onset of acute otitis media due to *Streptoccocus pneumoniae* or nontippable *Haemophilus influenzae* (37). Upper respiratory viral infections which may coexist during the episodes of acute otitis media did not significantly influence the concentrations of S100A12 protein, but the authors noticed a decreasing level of S100A12 protein in children who recovered from acute otitis media (37).

Up to the present, no consensus regarding the reference values for serum levels of S100A12 protein has been reached. Using enzyme-linked immunosorbent assay (ELISA), several authors reported mean serum S100A12 protein levels in healthy adults ranging from 10.7 to 75.0 ng/mL (38-41). Liu *et al.* were the first to provide a reference value for serum S100A12 protein levels in children: the mean serum concentration was 12.1 ng/mL ± 19.8 ng/mL in normal healthy subjects and 36.7 ± 72.4 ng/mL in children with acute otitis media (37). More recently, Hinze *et al.* reported a mean value of 44 ng/mL for S100A12 protein levels in healthy individuals aged between 4 to 20 years old (42). Recently, Pichichero *et al.* proposed a biomarker score based on age at diagnosis and serum concentrations of S100A12 protein and IL-10, which enables the clinicians to distinguish between upper respiratory infections with and without middle ear involvement

(43). However, further studies are required to fully understand the mechanisms involved in the activation of S100A12 protein in AOM and its implications in the development of the disease.

Limitations of the study

There are a number of limitations in this study that ought to be acknowledged. A major limitation of this study is the small sample size, but in pediatrics it is often difficult to recruit a high number of participants for research purpose basically due to ethical issues (44). Moreover, we recruited less patients than expected probably due to the lower incidence of the AOM in the Covid-19 era. There are several studies reporting a reduction in the incidence rate of AOM during the pandemic era and probably the protective measures we adopted to combat Covid-19 (45, 46). Another limitation is the lack of serum re-evaluation after the antibiotic treatment. This was mainly due to the favorable evolution of AOM cases, which did not require another blood sample to confirm the efficacy of the treatment. Also, it would have been useful to have the microbiological spectrum of the middle ear effusions, but a tympanocentesis was not routinely performed as it is an invasive procedure which weather was not recommended by the ENT specialist, or the parents were often reluctant to accept additional or invasive investigations.

CONCLUSIONS

Our study reveals that the inflammatory response related to AOM may be rather specific, than global, as the serum levels of IL-6 were higher in AOM group than in healthy controls ($p<0.001$), but with no significant difference regarding serum S100A12 protein between the two groups. Therefore, IL-6 could offer a powerful tool for the objective evaluation of AOM. IL-6 plays an important role in the pathogenesis of AOM in children, through its pro-inflammatory and immune-modulatory effects. Further research is needed to fully elucidate the role of IL-6 in AOM and to determine whether it may be a useful biomarker for predicting treatment outcomes.

Although it is only theoretical at this point, this different response may be specific to the children prone to AOM, and further studies are needed in order to establish if the risk of developing AOM is related to specific cytokine responses. Understanding the intracellular intricacies in relation to inflammation may contribute to newer therapies for AOM and even to the reduction of the complications and economic burden. We are hopeful that advances in the understanding of the inflammatory background of AOM may provide opportunities to create more targeted and effective treatments in the future.

Abbreviations

AOM: acute otitis media, CRP: C-reactive protein, ESR: erythrocyte sedimentation rate, HRP: Avidin-Horseradish Peroxidase, IL-1α: Interleukin-1α, IL-1β: Interleukin-1β, TNF-α: Tumor necrosis factor, IL-6: Interleukin-6, IL-8: Interleukin-8, OD: optical density, LPS: lipopolysaccharides.

CONFLICT OF INTEREST AND FUNDING

The authors declare no conflict of interest. This article was co-funded by the European Social Fund-the Human Capital Operational Programme, project/grant No: POCU/ 993/ 6/ 13/ 154722.

THE FOLLOW-UP OF PATIENTS WITH SURGICAL SOLITARY KIDNEY-THE UNDERESTIMATED ROLE OF COBORBIDITIES (Abstract): In order to customize the follow-up plan and lower the risks of end-stage renal disease progression (ESRD), we set out to create a monitoring program for patients with surgical solitary kidneys. Additionally, by determining the underlying etiology and comorbidities (such as pre-existing CKD or Diabetes). 91 patients have been found who satisfy the inclusion requirements. **Material and methods:** There were 51 ladies and 40 guys among them. They ranged in age from 20 to 90. The average age was 60.69 years (SD +/- 15.87). There was no difference in the mean age between the genders (63.22 *vs.* 58.71, p=0.08). Kidney cancer (50.54%), upper urothelial tract carcinoma (25.27%), pyonephrosis (17.58%), and kidney trauma (6.59%) were the primary pathologies for which surgery was performed. The patients were also arbitrarily separated into three age groups: Group A, 20-40 years old; Group B, 41-60 years old; and Group C, over 60 years old. **Results:** One month after discharge, C-reactive protein increased (p=0.05), and eGFR decreased significantly (p=0.003). The most common comorbidity (74.72%; n=68) was arterial hypertension. Of these, 51.47% (n=35) have diabetes mellitus concurrently. Diabetes was the second-highest occurrence, with 49.45% (n=45) of patients receiving therapy for it. Also, at the time of surgery, 12.08 % (n=11) had CKD, according to KDIGO definition. Since acquired solitary kidney patients are more likely to experience rapidly declining renal function, they require continuous monitoring. **Conclusions:** Younger individuals are more prone to develop CKD slowly. Therefore, the clinician has to monitor issues like kidney stones or urinary tract infections. **Keywords:** SURGICAL SOLITARY KIDNEY, COMORBIDITIES, CHRONIC KIDNEY DISEASE.

In patients with acquired solitary kidneys, reduced renal mass causes higher intraglomerular pressure and glomerular hyperfiltration, including individuals who have undergone unilateral nephrectomy for living kidney donation, renal cancers, or trauma. These physiological modifications to the single kidney may aggravate other inherited and pre-existing diseases that might increase glomerular disorders or establish susceptibility to them, leading to adverse renal outcomes. According to Brenner *et al.*'s hypothesis from the 1980s, a patient is more likely to develop hyper-

tension, proteinuria, and a long-term reduction in glomerular filtration rate (GFR) if they have fewer nephrons (1). A growing body of research indicates that a congenital or acquired decrease in renal mass is associated with a higher risk of renal impairment. Nephrosclerosis and nephron hypertrophy might have a significant role in CKD and mortality. However, studies on the effects of these microstructural traits have only been conducted on tiny tissue specimens from people chosen for either having healthy kidneys or renal disease. To investigate kidney structure-outcome relationships, patients with radical nephrectomy (often renal cancer) represent a special cohort. These people are chosen neither for the lack of nephropathy (such as live kidney donors) nor for the presence of nephropathy (such as those who have had a nephrologist perform a biopsy), despite the fact that they frequently have major comorbidities. We aimed to develop a monitoring program for patients with solitary kidneys in order to personalize the follow-up scheme, thus minimizing the risks of end-stage renal disease progression (ESRD) based on comorbidities at the moment of nephrectomy and after. (e.g., Diabetes Mellitus-DM, pre-existing chronic kidney disease-CKD)

MATERIAL AND METHODS

Even if, at first glance, the patient with a solitary kidney, especially those who do not have surgical history, should be monitored by a nephrologist, we believe that multidisciplinary management is needed. We initiated a prospective follow-up program for this group of patients in our hospital. We enrolled patients with surgically single kidneys (after high urothelial tumors, parenchymal tumors, pyonephrosis, renal trauma, etc.) who underwent nephrectomy between February 2022 and February 2023. Exclusion criteria have been represented by: pregnancy, age under 18 years, and lack of compliance. We collected demographic data, personal history, chronic medication, and biochemical parameters. The last item was evaluated in patients who underwent nephrectomy before the surgery, after one week, and after one month. We realized the statistical analysis using the ANOVA, chi-square, and t-Student tests. A p-value of < 0.05 was considered statistically significant. We have also used *IBM SPSS Statistics version 27.0.1.0* for our statistical analysis.

RESULTS

We have identified 91 patients who meet the inclusion criteria. Of these, 40 were males, and 51 were females. They were aged between 20 and 90 years. The mean age was 60.69 (SD+/- 15.87) years. The mean age was not different between the genders (63.22 *vs.* 58.71, p=0.08). The evolution of the biochemical parameters preoperatively, before discharge, and one month after discharge is represented in first table.

The main pathology for which surgery was performed was kidney cancer (50.54%), upper urothelial tract carcinoma (25.27%), pyonephrosis (17.58%), and kidney trauma (6.59%). We also arbitrarily divided the patients into three age groups: Group A, 20-40 years; Group B, 41-60 years; and Group C >60 years old.

We compared the values of serum hemoglobin, creatinine, C-reactive protein, and eGFR between groups, as shown in Table II.

We have identified the several comorbidities. Arterial hypertension was the most frequent encountered, 74.72% (n=68) patients were diagnosed. Of which 51.47%

(n=35) simultaneously having diabetes mellitus. This condition was the second most frequent encounter, 49.45% (n=45) of patients receiving treatment for it. Both are well known kidney injury elements even in patients without a history of nephrectomy. Before surgery, 12.08 % (n=11) had CKD, according to KDIGO definition (<60 mL/min/1.73 m^2 in the last three months). As shown in Table II, most patients diagnosed with this conditions had over 60 years of age (group C).

TABLE I.

Evolution of biochemical parameters

	Preoperatively	Before discharge	One month after discharge	p
Hemoglobin (g/dL)	11.96 (+/-2.51)	10.85 (+/-2.18)	11.76 (+/-1.65)	0.005
Serum creatinine (mg/dL)	1.78 (+/-2.04)	1.67 (+/-1.58)	1.46 (+/-0.71)	0.600
Serum urea (mg/dL)	45.38 (+/-25.09)	44.10 (+/-24.82)	41.39 (+/-19.59)	0.680
C-reactive protein (mg/dL)	40.59 (+/-64.13)	75.45 (+/-76.46)	18.58 (+/-26.86)	0.001
eGFR (mL/min/1.73m^2)	65.54.(+/-32.34)	56.70 (+/-22.40)	59.25 (+/-26.24)	0.130

TABLE II.

Biochemical parameters one month after discharge according to the age-group

	Group A	Group B	Group C	p
No of patients	11	28	52	
Hemoglobin (g/dL)	11.95(+/-1.72)	12.07(+/-1.84)	11.55(+/-4.5)	0.640
Serum creatinine (mg/dL)	1.02(+/-0.2)	1.41(+/-0.71)	1.58(+/-0.76)	0.270
C-reactive protein (mg/dL)	12.58(+/-8.76)	12.16(+/-9.65)	22.19 (+/-33.52)	0.050
eGFR (mL/min/1.73m^2)	95.67(+/-7.94)	63.89(+/-31.82)	46.41(+/-21.6)	0.003
Arterial hypertension (n)	2	16	50	0.0001
Diabetes mellitus (n)	2	11	32	0.034
CKD	1	3	7	0.280

DISCUSSION

In the past decades, much research has been done on the possibility of reduced renal function in solitary kidneys. Numerous clinical studies, mostly on people with congenital renal illness, have been undertaken to validate physiopathological results in animal models. Congenital solitary kidney patients had a considerably increased probability of needing dialysis, according to a retrospective assessment by Sanna-Cherchi *et al.* (2). This finding raises the possibility that subclinical solitary kidney anomalies are to blame for the worsened renal outcome. Previous observational studies have looked at the short- and long-term renal outcomes of living kidney donors. According to certain longitudinal investigations of living kidney donors, renal function had been well-maintained following unilateral nephrectomy, with a mean follow-up duration of 10.7 years to 25 years (3). Studies have shown that individuals with solitary kidneys have an in-

creased risk of developing kidney stones compared to those with two functioning kidneys. The exact incidence can vary widely, but research suggests the risk is significantly higher in this population.

CKD progression in patients with solitary kidneys has been studied, especially in children. Groen In't Woud S *et al.* evaluated 944 patients (children) diagnosed with a single functional kidney (congenital and acquired) (4). At the end of the study, 553 (59%) patients presented at least one indicator for renal failure (≥1 indicator of kidney injury), and 255 (27%) presented at least one indicator for severe renal failure. Akyol *et al.* in a cohort of 101 children, 71 with congenital single kidney (of which 55 with unilateral renal agenesis and 16 with polycystic dysplastic kidney) and 30 with acquired single kidney (17 with unilateral nephrectomy for renal tumor and 13 urological structural anomalies) highlighted renal injury in 9 (9%) of the patients and a positive correlation between uric acid concentration and renal injury. In adults, Argueso *et al.* performed a study on 157 patients with unilateral renal agenesis (5). The authors showed that 7 (19%) of 37 tested patients developed proteinuria (>150 mg/24h), 22 (47%) of 47 tested patients developed hypertension, and in 4 (13%) of 32 tested patients, renal function (creatinine) it degraded. At the end of the study, 43 (27%) patients died, 6 (4%) were due to renal failure. Xu *et al.* studied 118 patients with unilateral renal agenesis. At the initial evaluation, 14 (11.9%) had additional abnormalities, 15 (12.7%) had a heredocolateral history, and 30 (25.4%) presented with renal failure. They concluded that renal failure is common in patients with unilateral renal agenesis and that family history is a risk factor for severe renal failure (6).

Although, according to Worcester *et al.*, nephrectomy does not negatively impact stone disease, it may decrease renal function among younger males(7). In our study, patients over 60 years had more often comorbidities that could lead to kidney stones (8). Some of these conditions are known to worsen CKD. Kiberd *et al.* evaluated 381 transplant patients, in which they diagnosed 111 (29%) cases of diabetes, of which 17 were considered to have pre-existing diabetes, and 94 were new cases (31 transient, 63 fixed) (9). Alfandary *et al.* evaluated 353 patients with solitary functional kidneys (10). Compared to the control group, the prevalence of renal injury is higher at 42.2% *vs.* 23.5%, hypertension at 31.7% *vs.* 23.1%, proteinuria at 18.2% *vs.* 0.4%, and eGFR at 12.0% *vs.* 0.1 %. They concluded that a solitary kidney is associated with a significant risk of renal injury. Obesity is also a major modifiable factor for kidney injury.

According to Ellis *et al.*, nephrectomy can have unfavorable effects and induce progressive eGFR drop in individuals with preoperative CKD and in patients without preoperative CKD who later develop postoperative CKD. This is due to poor nephron mass reduction adaption or underlying kidney injury. This damage has been recognized in patients with clinically-evident CKD prior to nephrectomy. This damage may not be present, may only be modest, and may never have become symptomatic in individuals who did not have clinically obvious CKD prior to nephrectomy. Nephrectomy alters this, and individuals are then categorized as having CKD. The difference in overall survival between the two groups (patients with CKD before surgery and patients with incident CKD after nephrectomy) could be attributed to lead-time

bias if patients who develop CKD after nephrectomy are thought to have had subclinical CKD before surgery. The sole difference between subclinical and clinically-evident CKD, assuming the underlying pathogenic mechanisms are thought to be fundamentally comparable, is the timing of the first occurrence. individuals with CKD that is clinically obvious before nephrectomy are more likely to have an earlier start of the underlying disease that causes CKD, making them more likely to die as a result of CKD than individuals who do not have CKD that is clinically evident until after nephrectomy (11).

The third underlying disease that led to nephrectomy was lithiasic pyonephrosis. Considering that kidney stones have a complex etiology and often we encounter a so-called "metabolically active lithiasis," the follow-up of the patients is even more justified (12). A screening of lithiasic patients could prevent hydronephrosis episodes, which, over time, have a negative impact on kidney parenchyma. Often hydronephrosis is accompanied by urinary tract infection, especially in high-volume stones (13,14). According to Naqvi *et al.*, infection outcomes in CKD patients are 3 to 4 times worse than in healthy subjects (15). Also, according to Shang *et al.*, patients with kidney have a 1.47 relative risk of developing CKD (16).

In light of this, the following pertinent query is: How does the mortality risk for patients with new-onset CKD following surgery compared to that of individuals with medical causes of CKD who do not have nephrectomy? Demirjian *et al.* partially addressed this using the Cleveland Clinic Surgical Registry dataset, comparing all-cause mortality and non-renal cancer mortality in patients with "medical/surgical" and "surgical" CKD (n=1,097 and 1,053, respectively), as well as a cohort of 42,658 patients with CKD that wasn't brought on by nephrectomy and were treated by nephrologists at the Cleveland Clinic (17). The claim that CKD brought on by surgical nephron reduction has less clinical importance than CKD brought on by other sources has a problem. Clinical recommendations' thresholds for CKD stages are based on the facts that 60 mL/min per 1.73 m^2 is almost half of the average person's maximal physiological eGFR, can be correctly discriminated against using estimating equations, and is linked to a higher risk of adverse outcomes (18).

In our opinion, patients who are more likely to develop lithiasis should be evaluated at 3 months. For those with urinary tract infections, monthly after administration of the treatment according to urine culture and antibiogram, while for those with associated pathologies (hypertension, diabetes etc.), six months evaluation is the most cost-efficient, with subsequent monitoring depending on the clinical manifestations.

CONCLUSIONS

Patients with acquired solitary kidneys need close follow-up because they are prone to rapidly decreasing renal function. Although, according to our data, serum creatinine and eGFR do not have a significant modification, one month after patients discharge, degradation will likely occur over time. In younger patients, CKD is likely to develop slower; the clinician needs to follow up on the conditions like kidney stones or urinary tract. We suggest that patients who are more likely to develop lithiasis should be evaluated at three months. In our opinion, the most important comorbidity that should be followed is

urinary tract infection, the doses and duration of the treatment being adapted for eGFR, but the others should not be neglected. patient education to avoid as much as possible any trauma to the single kidney must be included in the therapeutic plan.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

TRANSTHYRETIN CARDIAC AMYLOIDOSIS: PARTICULARITIES IN NORTH-EASTERN ROMANIA (Abstract): Transthyretin cardiac amyloidosis (ATTR-CA) is characterized by progressive thickening of both ventricles and interatrial septum. The diagnostic algorithm is based on a correlation between biomarkers, electrocardiography, ultrasonography and bone scintigraphy criteria. However, epidemiological data may offer a glimpse for a possible ATTR-CA even before other investigations. The aim of this study is to determine the profile of the ideal ATTR-CA patient based on patient's epidemiology. **Materials and methods:** 72 patients (suspected, accidentally diagnosed or diagnosed with cardiac amyloidosis) over the course of 7 years from the archive of the Nuclear Medicine Laboratory of "Sf. Spiridon" County Clinical Emergency Hospital were analyzed. ATTR-CA diagnoses was made by bone scintigraphy, reducing the group to 20 patients. Epidemiological parameters included: patient's gender, age, height, weight and provenance region. **Results:** Gender classification revealed an equal distribution among ATTR-CA positive patients, aged between 30-89 years old and from Iași County. Endomyocardial biopsy (gold standard method) is an invasive and not widely accessible method. Correlation between biomarkers, electrocardiography, ultrasonography and bone scintigraphy criteria represents the alternative method for diagnosing this rare disease. However, a profile of the standard ATTR-CA patient based on epidemiological data may offer a possible insight for directing the diagnosing algorithm to include this pathology. **Conclusions:** Epidemiological data may offer a possible profile of the standard patient that can be suspected of ATTR-CA, therefore increasing the accuracy of diagnosing this disease. **Keywords**: ATTR-CA, EPIDEMIOLOGY, BONE SCINTIGRAPHY.

Amyloidosis is considered to be a rare and hard to diagnose protein deposition disease. Its main characteristic is the accumulation in different organs and tissues of amyloid resulting, eventually in organ failure. There are more than 30 amyloidogenic proteins, however, only six can affect the normal function of the myocardium (1, 2, 3, 4). Cardiac amyloidosis is considered to be the most prevalent cause of restrictive cardiomyopathy and therefore being associated with heart failure but with preserved ejection fraction. An analysis made in the US over the course of 12 years has determined an increase in the prevalence of this disease, from 8 to 17 per 100,000 people,

with an incidence from 16 to 55 per 100,000 person-years. However, this increase can be explained by the increase awareness and improved diagnostic methods (5). The most frequent forms of cardiac amyloidosis are represented by transthyretin cardiac amyloidosis (ATTR-CA) or light chain (AL) (4).

ATTR-CA is characterized by the buildup of amyloid in both ventricles and inter-atrial-ventricular septum. Untreated, it can be fatal. The mechanism is based on misfolding the transport protein transthyretin resulting in its inability to perform this task and to deposit into different organs and tissues. ATTR-CA presents two subtypes: wild type (ATTRwt) and hereditary or mutation (ATTRh/ATTRm) (6) (fig. 1).

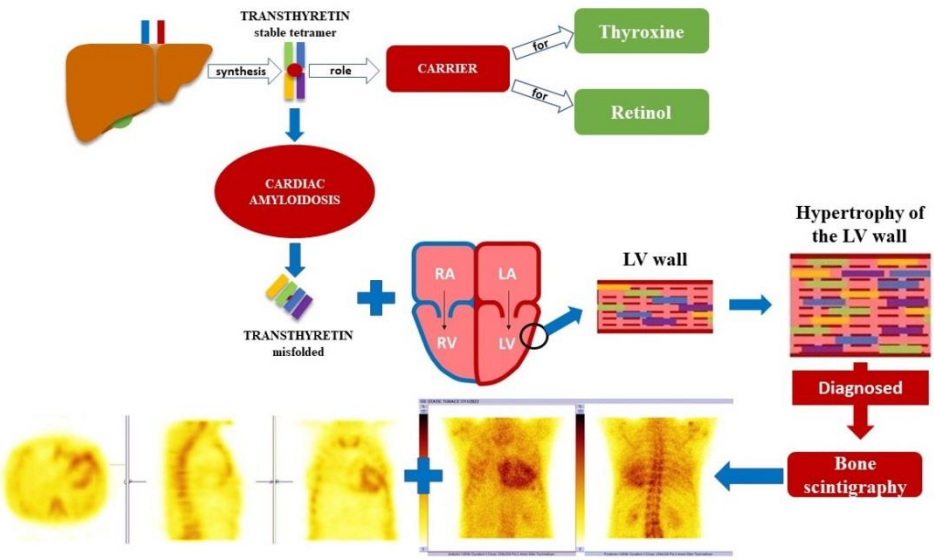

Fig 1. ATTR-CA mechanism and the relation with the functional image detection; (RA - right atrium; LA - left atrium; RV - right ventricle; LV - left ventricle)

The difficulties in predicting the incidence and prevalence for this disease are related to the complexities of the diagnostic process and not being able to rely on only one investigation to give the exact diagnosis all the time. Nevertheless, increased awareness for this pathology has proven to be important in the development of future medical therapies, such as the Transthyretin Amyloidosis Outcomes Survey which aims to characterize the course of the disease and the distribution worldwide. In the United Kingdom, over the past 2 decades, potential ATTR-CA cases have increased from 2% - 23.7% of new referrals, many of them being ATTRwt (5). A survey made an Italy which was based on 5315 ultrasonographies of patients over the age of 55 years old demonstrated a prevalence of 1%. However, by adding a few additional criteria such as increased wall thickness, a left ventricle ejection fraction over 50% and at least one ultrasonography red flag criteria for infiltrative disease, the prevalence was modified to 23.5% (7).

TTRwt affects especially the male pop-

ulation, presenting a male-female ratio of 25-50:1 (5, 8).

According to some articles ATTRwt affects approximately 25% of Finland's population and only 13% of Spain's. The ATTRwt positive patients in these articles, age wise, were over 85 years old (2, 9-11). Approximately 1 in 4 diagnosed patients is over 85 years old, presenting an average age of diagnosis of over 60 years old (5). The prevalence for this subtype being between 8-16%: 13% in patients with heart failure but with preserved ejection fraction; 16% in patients with aortic valve stenosis replacement; 30% in the subgroup of low-flow low-gradient stenosis and 5% of patients with hypertrophic cardiomyopathy (2, 9-12).

For ATTRh, the exact prevalence can be difficult to determine, mainly due to the variable geographical distribution of the mutation (6). From an epidemiological point of view, most of the patients are of male gender and with an average age between the 3rd and 8th decade. Mean survival rate depends on the mutation, however, it is considered to be approximately 3-12 years (13). However, in Europe it considered to be less than 1 in 100,000 and in Japan 1 in 1,000,000 (6). The most common mutations in ATTRh are: Val50Met and Val142Ile. Val50Met is found in male patients (male-female ratio of 2:1) ages ranging from 30-40 years in Portugal and 50-60 years in Sweden. It is considered to be endemic in Portugal, Sweden, Japan and Majorca (12). Untreated, mean survival rate is 26-46 months. It is considered that the origins of this particular subtype to be British, Cypriot, French, Greek, Italian, Japanese (5). Val142Ile is considered to be the most common variant worldwide presenting a prevalence of approximately 3.4% of African Americans. The origins seem to be from Africa, America and the Caribbean. The average age is over 65 years old: 20-39 years in Portugal, Sweden, Greece and Cyprus; 30-49 and over 60 years in Japan; average of 68 years in Britain, average of 64 years in France; average of 51 years in Italy (5, 6, 12, 14).

Due to the fact that ATTR-CA is a rare pathology, even with up-to-date methods for detection, any additional information can prove useful. The aim of the study is to determine ideal profile of the ATTR-CA patient based on the epidemiology data, for a more accurate detection.

MATERIALS AND METHODS

We performed a retrospective study based on data from the archive of the Nuclear Medicine Laboratory of "Sf. Spiridon" County Clinical Emergency Hospital, Iasi. Inclusion criteria were as follows: patients with the referral diagnosis of possible cardiac amyloidosis, positive bone scintigraphy for ATTR-CA, accidental diagnoses of ATTR-CA after bone scan. The study was made over the course of 7 years (2015-2022). Acquired epidemiological data included: age, gender and provenance region (in accordance with the identification card at that time).

ATTR diagnoses was determined after bone scintigraphy using the Perugini visual score and a semiquantitative method based on heart to contralateral and heart to rib ratios. All positive patients were recommended to undergo genetic testing.

All the patients were required to sign an informed consent in which full confidentiality was provided in case of publication. The

protocols that were used, were approved by the Ethics Committee of both the "Grigore T. Popa" University of Medicine and Pharmacy Iasi, Romania and "Sf. Spiridon" County Clinical Emergency Hospital, Iasi and therefore presented in the informed consent signed by the patient.

RESULTS

68 patients with the referral diagnosis of cardiac amyloidosis were initially included in the study. Bone scan diagnosed 16 patients with ATTR-CA. The remaining patients were classified as non-ATTR-CA patients that required further investigation to determine the diagnosis, 4 patients being eventually diagnosed with AL cardiac amyloidosis. To the ATTR-CA positive group, another 4 patients were added due to accidental diagnosis (other referral diagnosis) (fig. 2).

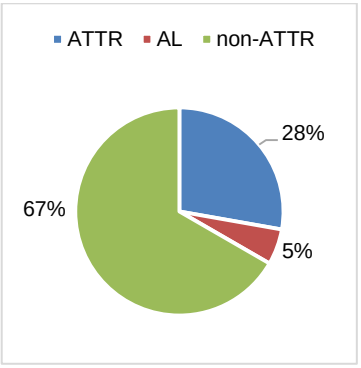

Fig 2. Patient distribution in accordance with the bone scan result (72 patients)

Gender and Age

Gender classification revealed an equal distribution among ATTR-CA positive patients: 10 male and 10 female patients (prevalence = 50%). Patients age varied from 35-89 years old. A more accurate distribution by age was obtained by classifying the patients per age decade (fig. 3).

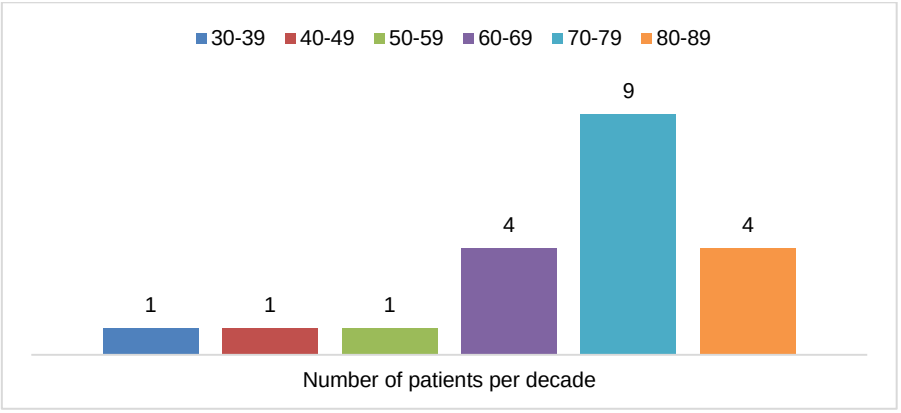

Fig 3. Patient distribution by age decade

Most of the patients were between 70-79 years old (prevalence = 45%).

Provenance region

All the studied patients were from the north-eastern region of Romania. Therefore, the ATTR positive patients were from the same region. Patient distribution was determined per county and not per city due to the fact that not all of the patients from one county were also from the same city (tab. I).

TABLE I.

Positive patient distribution per county and per total county population

County	Suceava (SV)	Bacău (BC)	Neamț (NT)	Vaslui (VS)	Iași (IS)	Botoșani (BT)
Positive patients per county	3	4	3	3	7	0

Most of the patients were from Iași County. (prevalence per positive patients = 35%)

Genetic testing

Genetic testing was performed only by 7 patients out of the entire ATTR positive group out of which 3 were diagnosed with ATTRwt and 4 with ATTRm (3 patients - GLU74GLN; 1 patient - VAL50MET).

Patient's particularities and correlations

Due to the fact that there is an equal number of males to female patients, the first filter that can be applied refers to the age of the patient. The results were as follows (tab. II):

TABLE II.

Correlation between gender and patients' age

Patients gender	Decades (years)					
	30-39	40-49	50-59	60-69	70-79	80-89
Female	1	1	1	1	4	2
Male	0	0	0	3	5	2

The majority of the ATTR positive patients where aged between 70-79 years old. Correlating this age with the gender revealed that most of them were males (male to female ratio = 1.25). The provenance region analysis determined that the focal area is Iași County. Genetic testing was also correlated with the patient's epidemiology data. For ATTRh, most of them where female aged between 35-52 years old. Provenance regions where Bacău (1 patient), Suceava (2 patients) and Iași (1 patient). For ATTRwt, most of the patients were females aged between 72-89 years old. Provenance regions where Bacău (1 patient), Iași (1 patient) and Vaslui (1 patient).

DISCUSSION

Over the years, ATTR-CA has proven to be a challenge for the practicing physician. The gold standard method for detecting cardiac amyloidosis refers to endomyocardial biopsy. However, this method is invasive and not widely available. To that end, the European Society of Cardiology offers an alternative for diagnosing this pathology, namely a correlation between biomarkers (NT-proBNP, troponin T) electrocardiography (micro voltage, left ventricular hypertrophy, pseudo infarct pattern, conduction and rhythm disorders), ultrasonography (left ventricular concentric hypertrophy; preserved left ventricular systolic function and ejection fraction; depressed longitudinal strain in the basal and midventricular sections with preservation of the apical one, reduced global longitudinal strain with apical sparing providing a specific appearance of "cherry on top" or "cupcake") and bone scintigraphy criteria (Perugini visual score and semiquantitative analysis). For positive cases, genetic testing is indicated for subtype determination. For negative results, free light chain dosage should be considered. The "red flags" offer a profile for the best candidate for cardiac amyloidosis, however, this profile must be sustained by other investigation methods (15).

In this research all of the patients were screened for a possible cardiac amyloidosis in the cardiology department, final diagnosis for ATTR being made by bone scan. To that end the researched focused to determine the characteristics from an epidemiological point of view of the ideal profile of the ATTR-CA patient. By evaluating the gender and age we were able to determine a possible profile for the ATTR-CA patient and compared our results to those present in the literature.

According to the "red flags", the ideal patient should be of male gender and over 65 years old. In our study, we obtained an equal number of ATTR positive patients regarding the gender (16). This can be explained by increased awareness of this disease in the last few years. Regarding the age of the patients, most of our patients were between 70-79 years old. Compared to the literature, these patients were detected in a later stage.

The provenance region represents one of the most important first steps that can determine the practicing physician to consider cardiac amyloidosis as a possible diagnosis. The obtained results revealed that in the North-Eastern region of Romania, the most affected county was Iași, followed by Suceava, Bacău and Neamț. The focal area for ATTR-CA in Romania is considered to be Suceava county (16). The provenance region of our group was based on the identification card, so it is conceivable that a change of address may have taken place at some point resulting in a balance shift towards a new region.

Based on the epidemiological data available data until this point the ideal ATTR-CA patient can be of either gender, aged between 70-79 years old and from Iași county.

However, some of the positive patients underwent genetic testing for subtype determination. Even though, the number of patients that underwent this test is small, it may offer an insight for a future research project. As a result, it was determined that out of the group of 20 ATTR positive patients, only 7 underwent genetic testing. Out of these 7 patients, 3 of them were diagnosed with ATTRwt and 4 of them with ATTRh (3 patients with GLU74GLN and 1 patient with VAL50MET). By applying the epidemiological filters stated above to these patients the results were modified. Therefore, for ATTRh, most of the patients were females, aged between 35-46 years old and from Suceava county. For ATTRwt most of the patients were females, aged between 72-89 years old. The provenance region, presented an equal distribution among Iași, Bacău, and Vaslui. These results underline the fact that for the hereditary subtype, the focal region is Suceava county, while for the wild type, this region is not included.

Therefore, if a patient, regardless of the gender, with an age between 35-46 and 70-79 years old and with a provenance region of either Iasi or Suceava county, then ATTR-CA may be suspected as a possible diagnosis. The two different intervals regarding the patients age, may be explained by the early onset of ATTR-CA symptoms in patients with the ATTRh subtype.

It must also be mentioned that due to the small number of positive patients, the risk of bias in our study may be present. The risk factor may require further validation in the future.

Nevertheless, a proper investigated background that includes the provenance region, in association with the gender and age interval for ATTR-CA may steer the practicing physician to consider this pathology as a possible diagnosis.

CONCLUSIONS

The first step in the diagnostic algorithm is the patient's epidemiology data. In this article, we tried to correlate the epidemiological data for ATTR-CA patients in order to give the practicing physician an edge. Therefore, a patient aged between 35-46 (especially ATTRh) and 70-79 years old, regardless of the gender coming either from Iași or Suceava should be considered as possible candidates for ATTR-CA. Based on the different age intervals an indication for the possible subtype involved can also be considered: ATTRh can be detected in an earlier stage compared to ATTRwt. Any kind of advantage in the detection algorithm of this rare disease should be taken into consideration for an early and more accurate diagnosis.

LONG-TERM RESULTS AFTER PRETARSAL FIXATION OF GOLD WEIGHTS IN FACIAL NERVE PALSY (Abstract) Chronic corneal exposure after facial palsy is a clinically condition requiring immediate treatment. The most effective and simple solution is the gold weight implant into the upper eyelid. **Aim**: to evaluate our long-term results using this method. **Materials and methods:** This is a retrospective study of the outcomes after pretarsal placement of gold weights in 20 patients operated by one surgeon from 2002 to 2020. **Results:** A total of 20 patients were included in the study. Follow up period ranged from 5 to 21 years. None of them have postoperative infections, ptosis, keratopathy, nor have they reduced visual acuity. Fifteen out of twenty patients have the implant in an adequate position, with appropriate lid closure. Two patients developed minimal implant migration and slight asymmetry, but implant remained functional and in place. Three patients developed important implant migration leading to extrusion. **Conclusions:** The results of our long-term study are similar to those revealed in the literature. Considering the favorable post-operative outcomes, we would recommend this technique for using either as a self-standing procedure or in conjunction with other static or dynamic procedures in facial palsy. For long term results and for improved migration and implant extrusion rates we recommend under correction by choosing to place the lighter implant instead of the "perfect", heavier implant. **Keywords:** FACIAL PALSY, CORNEAL EXPOSURE, GOLD WEIGHTS.

Chronic corneal exposure is a clinically condition requiring immediate and effective treatment. The primary cause of corneal exposure and lagophthalmos is facial nerve paralysis, occurring after facial nerve damage caused by trauma, surgery, infection, tumor, cerebrovascular events, or Bell's palsy (1). The dysfunction of the facial nerve severely impacts patient's emotional and psychological status, due to significant changes in the facial symmetry, having negative impact on the patient's quality of life. Ocular manifestations related to corneal exposure lead to cornea dryness, causing ocular discomfort, reduced vision, corneal ulcers, infection, and perforation. Maybe the most effective and simple solution for correction of paralytic lagophthalmos is the gold weight implant into the upper eyelid, associated or not to more complex, dynamic, or static facial reanimation method. The aim of this study is to evaluate our long-term results using this method.

MATERIALS AND METHODS

This is a retrospective study of the surgical outcomes after pretarsal placement of gold weights in 20 patients operated by one surgeon from 2002 to 2020. The collected data were the cause of facial palsy, the delay form the installation of the palsy to the implantation, the implantation technique, the weight of gold implant, additional lid and /or facial surgeries, and the post-operative complications. Results and evolution were photographically documented.

The gold weight implants used were either handcrafted (18 cases) or readily available (2 cases, MedDev Corporation) having a predefined weight from 1.2 to 1.8 grams with increments of 0.2 grams. In each case the preoperative calibration was performed using a Standard Tantalum Weight Sizing Set (MedDev Corporation).

Surgical technique is simple and straightforward. The patient is positioned supine with the head elevated at 30 degrees. We used local anesthesia (Lidocainum or Bupivacainum and adrenaline 1/100,000 injected subcutaneously), without sedation. Incision line is marked 6 mm from lid margin. A 1.5 cm long supra-tarsal incision is made through the skin and orbicularis oculi muscle, creating a pocket over the tarsal plate. The gold implant is centered and fixed to tarsal surface with three 6.0 polypropylene sutures. Eyelid eversion was performed to check the conjunctiva integrity. The wound was then closed in two layers with 6.0 resorbable sutures for the orbicularis and 6.0 nylon for the skin. The skin sutures were removed after 5-7 days. The patients were discharged same day. Follow-up was carried out at 48 hours, one week, one month, three months, six months, and on a yearly basis. The implant position and closure of the palpebral slit are checked on each examination by the plastic surgeon and corneal integrity is verified once a year by the ophthalmologist.

RESULTS

A total of 20 patients undergoing upper eyelid loading for lagophthalmos were included in the study. Follow up period ranged from 5 to 21 years. The mean age of our sample was 58 years, with an age range from 34 to 82 years. We had equal male / female distribution. The most common cause of the facial palsy was tumor in 16 patients including acoustic neurinoma (9 cases), cystic parotidean adenoma (3 cases), cholesteatoma (2 cases), and squamous cell carcinomas (SCC) (2 cases). Three cases of facial paralysis were post-traumatic, and one case was congenital. All patients had unilateral disease. All were operated after at least one year after facial palsy instalment. Twenty-seven operations were performed (20 for implantation, 4 for repositioning and 3 for final removal). We used 1.2 g implants in 2 cases, 1.4 g in 7 cases, 1.6 g in 8 cases, and 1.8 g in 3 cases (fig. 1).

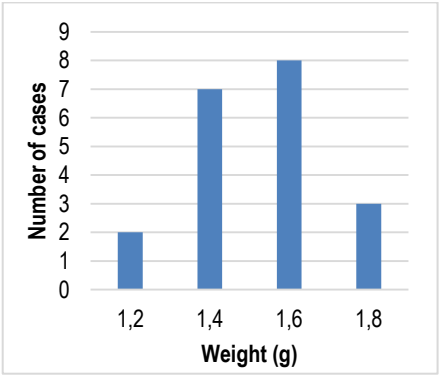

Fig. 1. Distribution of cases according to the weight of the implant

At the moment of the eyelid implant, 12 of the patients included in the study had already undergone at least one surgery on the eyelid or facial area in other hospitals (static only). Gold weight implantation was the only therapeutic option for 10 patients which denied any other type of surgical treatment for facial reanimation. Six patients needed dynamic reconstruction techniques (2 facial nerve reanimation, babysitter procedure with cross face nerve grafts, one with temporal tendon transfer, 2 with facial nerve grafting, and one with primary neurorrhaphy). Four patients needed additional static canthopexy for medial paralytic ectropion of the lower eyelid.

No intra-operative or early postoperative complications were registered. None of the patients have postoperative infections, ptosis, keratopathy, nor have they reduced visual acuity. Fifteen out of twenty patients have the implant in an adequate position, with appropriate lid closure since the surgery up to the latest follow-up. Two patients developed minimal implant migration and slight asymmetry, but implant remained functional and is still present. Three patients developed important implant migration leading to extrusion.

DISCUSSION

The eye closing inability results from the unopposed action of the *levator palpebrae superioris* muscle on the upper eyelid, which is normally contracted by the function of the orbicularis oculi muscle. The paralyzed eye can be conservatively managed with ointment, eye drops, moisture chambers, and lid taping. However, these methods may be difficult and cumbersome for most of the patients, and they provide suboptimal corneal protection. Ideally this should be only a temporary situation until the facial nerve is reconstructed by a dynamic method and the eye closure is restored. Unfortunately, and somehow inexplicably, there is still a vast majority of patients with long standing well documented facial palsies waiting for facial regeneration for many years. Moreover, they seem reluctant to complex functional surgeries preferring minimal interventions. Options for surgical management of the paralyzed eyelid in such cases include a variety of static techniques with variable degrees of success, such as tarsorrhaphy, canthoplasty, *fascia lata*, and silicone slings, palpebral springs. Very popular in Romania seems to be the simplest static methods like tight tarsorrhaphy (fig. 1) which might provide significant changes regarding corneal exposure, ocular surface symptoms but lead to poor aesthetics results or even disfigurements.

Weight implantation in the upper eyelid for treatment of the lagophthalmos in cases of facial paralysis was first described in 1950 by Sheehan *et al.* (2), and it was first used in 1958 by Illig *et al.* (3). Folded tantalum is the first material used as an implant. Gold was first used as a lid load in 1966, and it seemed to be “the most practicable material with its great range of colors and minimal reactivity in the tissues” (4). More materials emerged and have been used, such as stainless-steel mesh, lead, platinum and hyaluronic acid gel (2, 4, 5) The gold implant has the advantage of being relatively inert, providing an aesthetic camouflage, high density, and nonallergenic features. The complications of these implants include migration, soreness, persistent lagophthalmos (generally while sleeping), extrusion, and ptosis (6-10). Recently, platinum was used for lid loading as an alternative to the gold implant (11). Its advantages are the density (21.5 g/cm^3) which allows implants to be 10% smaller

than gold ones, better biocompatibility, flexibility and the reduced risk of extrusion and adverse reactions to the metal. However, despite these advantages, the gold implant remains the most used because of the accessibility and the price.

Although lid loading technique is simple the use of this method seems very limited in our country. We used gold weights for the management of the eyelid in facial palsy combining dynamic and static methods for lower middle and upper face with successful results.

All our patients had unilateral disease (figs. 2 A, B, C, and figs. 3 A, B, C). For the 20 eyelids reconstructed a number of 27 operations were performed (20 for implantation, 4 for repositioning and 3 for final removal). Seventeen patients had a single operation for implantation, 1 patient required 2 operation (implantation + removal), one patient had 3 operations (implantation, repositioning, and removal), and one patient underwent 5 interventions (implantation, 3 repositioning and 1 removal). All our patients in need for final removal arrived in clinic long time after implant exposure, and they denied any another implant or operation (figs. 4. A and B). In a retrospective cohort review on 104 gold weights in 94 eyelids, Rofagha (12) applied the Kaplan-Meier survival curve analysis and obtained 3% exposure rate at 12 months, 5% at 24 months, and 10% at 5 years, which increased to 35% at 153 months. Another study conducted by Kelly (13) reported a 68% complication rate, and the extrusion rate was 43 %. Our group shows a 15% extrusion rate after 5 - 21 years follow up. Since in our experience extrusion occurred secondary to a long period in which the patient neglected the doctor's recommendations in our opinion this complication is more related to the characteristic of the patient's skin and to the low adherence to treatment and less related to surgical technique.

Preoperative calibration (Standard Tantalum Weight Sizing Set, MedDev Corporation) was performed to establish the weight that induces the reduction of lagophthalmos without creating ptosis. Adhesive taped predetermined weights were attached to the pretarsal portion of the upper lid, while the patient was relaxed in a sitting position. We always start with the 1.2 grams weight for 3 to 5 minutes. The weight was increased by 0.2 grams until the proper result was obtained.

Fig. 2. A before implant, corneal exposure and tarsorrhaphy; B, C, eye closure after gold weight implant.

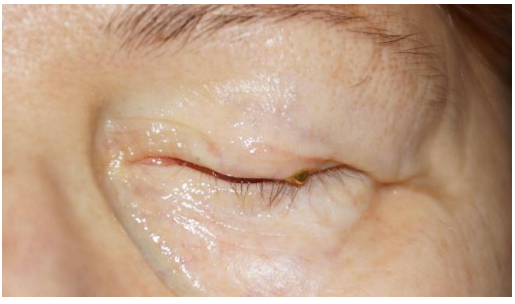

Fig. 3. A. Extrusion, before removal

Fig. 3. B. Extrusion, before removal

Corneal exposure was present in all patients before surgery. Postoperative, all twenty patients presented reduced corneal staining and within 2 to 4 weeks the corneal staining faded. Compared to the study conducted by Harrisberg *et al.* (6) our re-

sults are similar regarding the sustaining of corneal function and ocular comfort with the use of the lid gold implant. The corneal protection was maintained during the follow-up period. Although other authors (14, 15) aim a decrease in lagophthalmos from 4 to 5 mm preoperatively to 0.5 mm postoperatively, in our group, the rate of remaining long term lagophthalmos is 0.5 to 1.5 mm in all the cases as we aimed under correction allowing a slight corneal exposure (figs. 2 and 3) especially in previously operated cases. We consider that a smaller weight has les chances of extrusion.

The surgical technique evolved from the originally subcutaneous implantation of the gold weight 3,4 which was quickly waived due to the high rate of complications in favor of pre-tarsal fixation. Since there is a lack of evidence for the superiority of one technique of pretarsal fixation over another we used in all the cases the same technique: the size of the pocket is small enough to fit to the size of the gold weight and we place the knots of three permanent sutures into the holes of the plate. Migration is only possible if at least one of the 3 permanent suture points breaks. In a metanalysis Schrom *et al.* (7) highlights a complete eyelid closure rate of 84% but with a fairly high rate of complications which encourages the oculoplastic surgeons to consider alternative methods in terms of surgical technique. In our experience we achieved eyelid closure in 100% of the cases but with the same relatively high rate of complications, 15% (extrusion) compared to 6.8% extrusion and 6,4% migration.

Although lower placement of the gold weight might lead to a better functional result, we favor upper implantation since it seems to us it causes less damage to the eyelid tissues with less chances of extrusion. Nowak-Gospodarowicz (16) considers that combining lower placement of the gold weights about 2 millimeters above the eyelash line with absorbable sutures should be avoided due to the high risk of complications.

Preoperatively, all patients complained of foreign body sensation and ocular discomfort despite the use of lubricating eye drops and eye closure during the night. After upper lid loading, all 20 patients discontinued to use lubricant eye drops after a couple of postoperatively but used external eyelid closure during the night for several years. On the long run, out of the 20 patients operated, 3 had a remaining lagophthalmos (2 mm) located exclusively medial due to the ectropion which left a portion of the medial sclera exposed. The lagophthalmos was not present in patients which accepted lateral canthopexy. Comparatively, after placement of 104 gold weights in 94 eyelids, Rofagha and Seiff (12) obtained decreased lagophthalmos in 88 patients, and in the case of the remaining 6 patients, no improvement in lagophthalmos was observed. The principal cause for persistent lagophthalmos in their study was the eyelid scaring from other surgery or prior spring removal.

CONCLUSIONS

Gold weight implantation in patients with facial paralysis is a simple and reliable procedure with significant reduction in paralytic lagophthalmos and improvement of corneal coverage and obvious long-term cosmetic benefits. The results of our long-term study are similar to those revealed in the literature. Considering the favorable post-operative outcomes, we would recommend this technique for using either as a

self-standing procedure or in conjunction with other static or dynamic procedures in facial palsy. For long term results and for improved migration and implant extrusion rates we recommend under correction by choosing to place the lighter implant instead of the "perfect", heavier implant.

GLIOMA-RELATED EPILEPSY-CHARACTERISTICS AND IMPLICATIONS ON TREATMENT AND PROGNOSIS IN THE CONTEXT OF MOST RECENT BRAIN TUMOR MANAGEMENT GUIDELINES (Abstract): Diffuse low-grade gliomas, neoplasms originating from glial tissue, exhibit a propensity to evolve into tumors of a higher grade over time. The management of low-grade glioma presents a multifaceted challenge in clinical decision-making, given its complex diagnostic profile. Numerous factors have been identified as critical in determining the outcomes of various treatment modalities and in serving as prognostic indicators with predictive significance. Among these, glioma-associated epilepsy stands out as a principal clinical indicator, playing a pivotal role in both the management strategies and prognostication post-treatment. **Materials and methods:** A retrospective analysis was conducted on a cohort of 38 patients diagnosed with low-grade glioma (LGG), World Health Organization (WHO) grade 2 or 3, who were treated within our neurosurgical department from 2013 to 2023. This study primarily focused on the occurrence of glioma-related epileptic seizures. Additionally, an extensive review of the pertinent literature was undertaken to enrich the analysis. The evaluation encompassed the assessment of Engel outcomes six months following surgical resection, along with the examination of the anti-seizure medication (ASM) regimens implemented. Furthermore, a comprehensive review and synthesis of the current National Institute for Health and Care Excellence (NICE) guidelines pertaining to the management of low-grade gliomas were conducted, highlighting the latest recommendations and therapeutic strategies. **Results:** Within the cohort of 38 patients diagnosed with glioma, 30 were definitively identified as having diffuse astrocytoma (grade 2 and 3), while the remaining 8 were diagnosed with oligodendroglioma. Among those experiencing glioma-related epilepsy (n=25), a management approach involving biopsy only was applied to 8% (n=2) of the cases, gross total resection (GTR) was performed on 40% (n=10), subtotal resection (StR) was administered to 32% (n=8), and partial resection (PaR) was executed on 20% (n=5) of the patients. The investigation did not uncover a significant correlation between the occurrence of seizures and variables such as tumor volume, rate of growth, or histological findings. However, a notable positive effect of the extent of surgical resection on patient outcomes was observed, as measured by the Engel classification system, six months subsequent to oncological intervention. **Discussion:** Several researchers have illustrated that the presence of seizures during the initial stages serves as a favorable prognostic indicator for both malignant progression-free survival and overall survival

in patients diagnosed with glioma. Furthermore, the manifestation of epilepsy as a presenting symptom significantly impacts the quality of life of individuals afflicted with glioma. **Conclusions:** Exploration into a more intricate approach to epilepsy surgery specifically targeting glioma-related seizures could yield considerable advantages, with the potential to enhance the quality of life for patients post-treatment. **Keywords**: GLIOMA-RELATED EPILEPSY, LOW-GRADE GLIOMA, EPILEPSY SURGERY, ENGEL CLASSIFICATION, NICE BRAIN TUMOR GUIDELINES.

INTRODUCTION

Diffuse low-grade gliomas, classified as tumors originating from glial tissue, possess the inherent capability to evolve into higher-grade malignancies over time (1, 2). Consistent with established guidelines for glioma management, the patient's treatment trajectory post-diagnosis is recommended to adhere to a predefined algorithm. This commences with diagnostic procedures, prioritizing imaging techniques for the presumptive identification of glioma. Initial imaging should include a comprehensive structural MRI protocol, incorporating T2-weighted, Diffusion-Weighted Imaging (DWI), Fluid-Attenuated Inversion Recovery (FLAIR), and T1-weighted sequences both pre- and post-contrast administration. A consensus on the management strategy should be sought through discussion within a multidisciplinary team upon the initial imaging diagnosis. Furthermore, the deployment of advanced MRI methodologies, such as MR perfusion and MR spectroscopy, is advocated where feasible, to facilitate the identification of potential high-grade transformations within gliomas that may initially present as low-grade on standard structural MRI scans (3) (fig. 1).

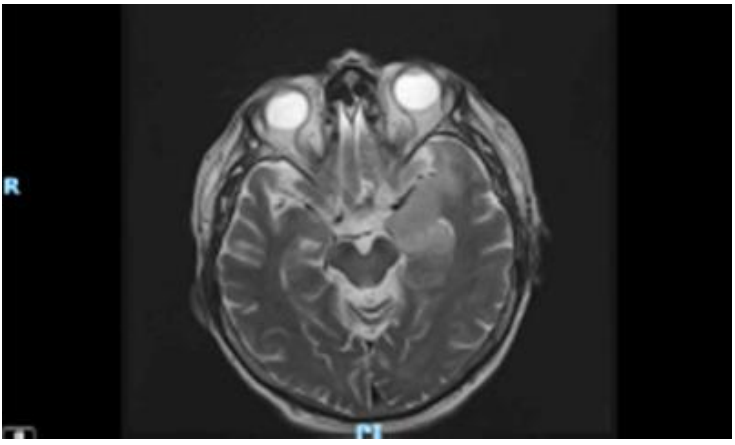

Fig. 1. Axial T2W images of 69M with WHO grade 2 diffuse astrocytoma (Left Temporal Lobe)

The management of glioma should incorporate surgical resection ideally within a six-month period following the imaging diagnosis. The primary objectives of the initial surgical intervention are to secure a histological diagnosis and to excise as

much of the glioma as is feasibly safe, subsequent to a thorough and thoughtful deliberation with the patient and their kin. In instances where surgical resection is deemed infeasible, pursuing a biopsy for histological determination is advised. Additionally, the option of active surveillance without histological confirmation may be considered, albeit exclusively for tumors exhibiting characteristic imaging signatures of low-grade tumors, such as Dysembryoplastic Neuroepithelial Tumors (DNET) or optic pathway glioma. Facilities specialized in neurosurgery for glioma treatment should be equipped with at least some advanced operational capabilities, including but not limited to, the ability to conduct awake craniotomies with language and functional monitoring, intra-operative neurophysiological monitoring, and intra-operative imaging guidance (3).

The surgical approach to glioma management necessitates the incorporation of various contemporary guideline recommendations to enhance treatment efficacy and patient safety. The use of 5-aminolevulinic acid (5-ALA)-guided surgery is recommended as a significant adjunctive measure to enhance the extent of resection during the initial surgery of gliomas that are radiologically suspected to be high-grade. Furthermore, the employment of intraoperative magnetic resonance imaging (MRI) is advocated to facilitate the precise removal of tumor tissue while concurrently preserving neurological function. The integration of intraoperative ultrasound and diffusion tensor imaging (DTI), alongside traditional neuro-navigation methods, is crucial for minimizing damage to critical neuronal pathways. Additionally, the execution of awake craniotomy stands out as a paramount technique for the maximal preservation of neurological functions, necessitating the involvement of neuropsychologists and speech and language therapists to ensure optimal outcomes. This comprehensive and nuanced surgical strategy underscores the importance of employing advanced technological interventions and multidisciplinary collaboration in the management of glioma, aiming to achieve the best possible patient-centric outcomes.

Within the realm of contemporary advancements in the treatment of brain tumors, laser interstitial thermal therapy (LITT) emerges as a noteworthy mention, having been progressively recognized as a minimally invasive therapeutic modality (4). Research conducted by Hawasli *et al.*, in 2013 (5), has validated LITT as a secure and efficacious ablative approach for addressing intracranial lesions, while also acknowledging the potential morbidities associated with its use, such as aphasia, hemiparesis, hyponatremia, meningitis, and deep vein thrombosis (DVT).

Moreover, the employment of molecular markers has become instrumental in the prognostication and therapeutic stratification of glioma. Notable markers include IDH1 and IDH2 mutations, ATRX mutations (pertinent to IDH mutant astrocytomas and glioblastomas), 1p/19q codeletion (indicative of oligodendrogliomas), histone H3.3 K27M mutations (associated with midline gliomas), and BRAF fusion and mutations (relevant to pilocytic astrocytoma) (3).

In the intricate landscape of glioma pathology, significant effort has been devoted to identifying and delineating factors that profoundly impact the quality of life of individuals diagnosed with this condition. Through a retrospective examination of cases handled within our neurosurgical

department, it has been observed that patients who presented with or developed epileptic seizures postoperatively experienced a notable deterioration in their quality of life. This adverse impact extends beyond physical health, exerting a considerable psychological burden on the affected individuals over both short and long-term periods.

Per the National Institute for Health and Care Excellence (NICE) guidelines, the management of epilepsy or seizure control is identified as one of the three paramount outcomes following glioma surgery, alongside progression - free survival and neurological function (assessed via the Neurological Function Scale or NIH Stroke Scale). These outcomes have been recognized as pivotal in assessing the risks associated with the decision to proceed with or forego tumor resection. Among these, progression-free survival is deemed to hold greater importance over overall survival, as it more accurately reflects the tumor-specific outcomes influenced by the decision to ablate the tumor (3).

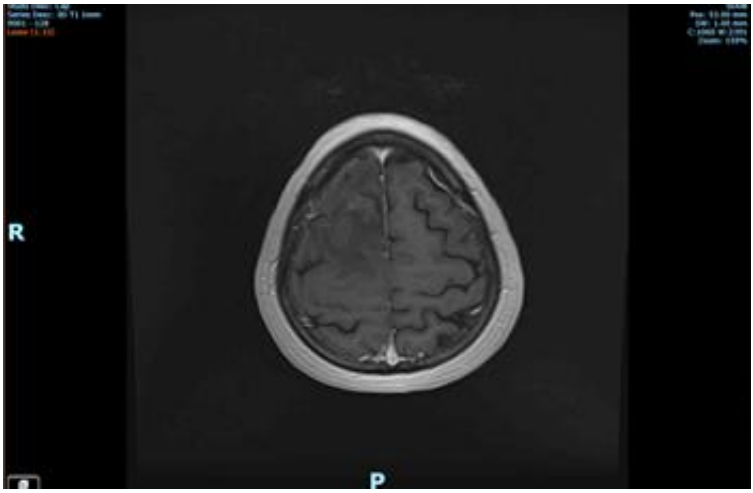

Fig. 2. Axial T2W images of 61F with WHO grade 3 astrocytoma (Frontal area)

Epileptic seizures presenting as initial symptoms significantly affect the quality of life for individuals diagnosed with glioma. Various studies have sought to identify factors influencing the incidence of epileptic seizures during the neurosurgical perioperative period, as well as potential interventions to enhance epilepsy-related outcomes in patients undergoing glioma surgical resection (6). Seizures typically manifest first in patients who are later diagnosed with glioma, particularly those with low-grade gliomas located in the frontotemporal regions, which are associated with an elevated risk of postoperative seizures. The presence of drug-resistant epilepsy (DRE) and notable peritumoral edema are linked to a higher occurrence of peri-operative seizures, whereas gross total resection has been shown to diminish the incidence of postoperative seizures (6) (fig. 2).

The Engel system is employed for classifying epilepsy outcomes following surgery, originally developed for assessing results in patients after epilepsy surgery (7).

TABLE I

Engel classification of postoperative outcome (Engel 1993) (7)

Class	Characteristics
Class I	Free of disabling seizures
	A: Completely seizure-free since surgery B: None disabling; simple partial seizures only since surgery C: Some disabling seizures after surgery, but free of disabling seizures for at least 2 years D: Generalized convulsions with AED discontinuation only
Class II	Rare disabling seizures (“almost seizure free”)
	A: Initially free of disabling seizures but rare seizures now B: Rare disabling seizures since surgery C: More than rare disabling seizures since surgery, but rare seizures for the last 2 years D: Nocturnal seizures only
Class III	Worthwhile improvement
	A: Worthwhile seizure reduction B: Prolonged seizure-free intervals mounting to greater than half the followed up., But not<2 years
Class IV	No worthwhile improvement

MATERIALS AND METHODS

A retrospective analysis was conducted on a cohort of 38 patients diagnosed with low-grade gliomas (LGG), WHO grades 2-3, who were treated in our neurosurgical department over the decade spanning 2013 to 2023. This analysis placed a particular emphasis on the incidence of glioma-related epileptic seizures, supplemented by a thorough review of pertinent literature on the subject. The study evaluated the Engel outcome six months post-resection, in addition to reviewing the anti-seizure medication (ASM) protocols employed.

Our neurosurgical department, situated within the Emergency University Hospital (SUUB) in Bucharest, serves an approximate population of one million individuals. Glioma cases are typically referred to our department either through the General Practitioner service or by direct admission via the Accident and Emergency Department. Upon a clinical and radiological presumptive diagnosis of a central nervous system (CNS) tumor, patients are integrated into a clinical pathway that includes Neurosurgery, Neuroradiology, and Oncology. This multidisciplinary team approach is facilitated by weekly meetings, known as the “Tumor Board,” at the Emergency University Hospital Bucharest.

The scope of our investigation encompassed a comprehensive review of clinical and imaging data, diagnostic approaches, and treatment modalities from 2013 to 2023. This review included an analysis of surgical procedure records, patient clinical notes, histology findings, and outpatient follow-up clinical data for all patients diagnosed with diffuse low-grade glioma. Parameters such as patient age, gender, initial presenting symptoms, lesion locali-

zation, eloquence, the occurrence of epileptic seizures, adjuvant treatments, as well as pre-operative seizure characteristics (type, duration, and frequency) and post-operative Engel classification outcomes were meticulously examined (fig. 3).

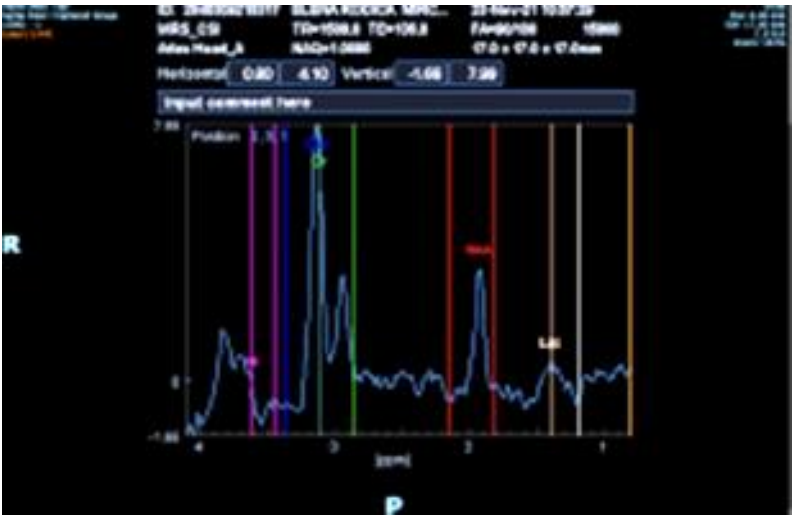

Fig. 3. MR Spectroscopy of 37F with WHO grade 3 oligodendroglioma

The analysis of preoperative and post-operative imaging focused on various dimensions, including the glioma's location, lateralization (dominant vs. non-dominant hemisphere), eloquence, and distinctive features observed in MR spectroscopy sequences, particularly the choline/N-acetyl aspartate (Cho/NAA) high ratio. Additionally, the study examined the correlation between the variability of peritumoral edema, as evidenced on imaging, and the incidence of epileptic seizures.

MRI examinations discussed in this research were conducted within the Radiology Department of the Emergency University Hospital Bucharest, serving both as an integral component of the preoperative diagnostic process and as part of the post-operative follow-up regimen.

RESULTS

Among the 38 patients diagnosed with glioma, 30 were conclusively identified with diffuse astrocytoma (grades 2 and 3), while 8 were diagnosed with oligodendroglioma. The median age of the cohort was 50 years old, with females comprising 60% of the patient population. Tumor localization was diverse: frontal lobe (n=24), temporal lobe (n=6), parietal lobe (n=6), and insular region (n=2). The majority of gliomas (n=28) were situated in the dominant hemisphere, with the remainder (n=10) in the non-dominant hemisphere. Presenting symptoms varied widely, including asymptomatic cases (n=3), motor deficits (n=16), visual deficits (n=2), seizures (n=25), aphasia (n=9), and intracranial hypertension (n=6).

Surgical interventions were categorized as follows: biopsy only (n=6), gross total resection (GTR) (n=14), subtotal resection (StR) (n=10), and partial resection (PaR) (n=8).

Regarding glioma-related epilepsy (n=25), management strategies included biopsy only (8%, n=2), GTR (40%, n=10), StR (32%, n=8), and PaR (20%, n=5). Seizure presentation varied from simple partial (focal) seizures to complex generalized tonic-clonic seizures, with seizure frequency ranging from daily to monthly prior to diagnosis. Beyond surgical resection, seizure management involved anti-seizure medication (ASM) from the initial presentation, adhering to standard guidelines. In complex epilepsy cases, specialized adjustments to ASM types and doses were necessary. The most responsive treatments involved Carbamazepine, Levetiracetam, Valproic acid, Topiramate, Phenytoin, or Lamotrigine, with combinations used for more complicated cases.

The study found no significant correlation between seizure presence and tumor volume, growth rate, or histological findings. However, the extent of surgical resection significantly influenced outcomes, as determined by the Engel classification system, six months post-treatment. Notably, 76% of patients undergoing maximal resection were seizure-free (Engel class IA) at the 6-month mark, whereas 20% of those with StR achieved Engel class IA, and 46% reached Engel Class IIB during the same follow-up period.

DISCUSSION

In examining the scholarly work pertaining to epilepsy associated with glioma, it is critical to acknowledge the nuanced impact of epilepsy on patients with glioma. Despite the adverse effects on quality of life, several pieces of research have underscored the prognostic significance of epilepsy in individuals with glioma (1). These studies underscore the necessity of further research into the prognostic implications of epilepsy in patients diagnosed with diffuse low-grade glioma, calling for extensive cohort analyses over extended follow-up periods. A notable study, utilizing a large patient cohort (1,509) from a multi-centric French national database, incorporated a variety of variables to explore both spontaneous and post-treatment seizure risk predictors, as well as the prognostic relevance of epileptic seizures. This research aimed to comprehensively assess the impact of epileptic seizures on the diagnosis and progression of diffuse low-grade glioma, in addition to evaluating the influence of such gliomas on the incidence of epilepsy, whether as a preoperative or postoperative condition (1).

Concurrent efforts are directed towards attaining a more profound and intricate comprehension of seizure mechanisms within the glioma context and the innovation of next-generation anti-seizure medications (ASM). Tripathi *et al.*, 2024 (8), delve into the proinflammatory immune dimension of epilepsy, contrasting it with the immunosuppressive milieu observed in patients experiencing glioma-related epilepsy. According to their findings, the epileptic condition characterized by excessive neuronal activity is proposed to encourage immunosuppression, thereby exacerbating glioma progression. The study highlights the IDH1 mutation’s role in metabolic modulation, offering a dual approach to counteracting immune suppression and diminishing seizure occurrences. This insight into the interplay between neuronal activity and immune responses presents a promising avenue for the development of advanced anticonvulsant therapies (8).

Pallud *et al*., 2014 (1) elucidated that risk factors for seizures in the initial stages of glioma are predominantly associated with the tumor's topographic location and its eloquence. Additionally, the presence of other symptoms, such as neurological deficits and increased intracranial pressure, does not favor the control of epileptic seizures, which, paradoxically, may not improve but rather deteriorate over the natural progression of diffuse low-grade glioma. The control of seizures post-treatment is likely influenced by the glioma's topographic characteristics and the extent of surgical resection. Notably, the initial presence of seizures is identified as a positive prognostic indicator for malignant progression-free survival and overall survival.

Avila *et al*., 2017 (9) posited that employing an epilepsy surgery strategy, including preoperative invasive recording in patients with brain tumor-related epilepsy (BTRE), could significantly aid in delineating the epileptogenic zone, potentially leading to enhanced Engel outcomes. Furthermore, for tumors located in the temporal lobe, such as dysembryoplastic neuroepithelial tumor (DNET) or ganglioglioma, a temporal lobectomy coupled with hippocamp-ectomy is suggested to yield a more favorable seizure prognosis than merely excising the lesion.

The approach to surgical management in glioma encompasses a paradigm distinctly different from that applied in focal non-tumor related epilepsy surgery, which often incorporates direct cortical recording or extra-operative invasive techniques. These methods are generally not utilized in glioma surgery, indicating a potential area for further research to ascertain their utility in enhancing seizure outcomes for glioma patients (9).

The exploration of a possible link between molecular markers and epilepsy in glioma remains a critical and imperative field of study. Some research suggests that seizures associated with glioma may not necessarily be triggered by specific tumor characteristics (10). It has been demonstrated that seizures typically originate from the peritumoral neocortex, where infiltrated glioma cells pervade (11).

Recent advancements in the identification of non-invasive pre-operative tumor markers have markedly progressed, poised to revolutionize the rapidly evolving cancer treatment paradigm. Innovations in imaging techniques, such as the apparent diffusion coefficient (ADC), cerebral blood volume (CBV), and the identification of T2FLAIR mismatch, are set to enhance the diagnostic capabilities in the pre-operative phase (12, 13) (fig. 4).

A pivotal concern in the management of gliomas pertains to the progression observed following radiotherapy treatment. This area of discussion is particularly relevant for cases that demonstrate radiological signs of tumor progression at varying intervals after undergoing radiotherapy, with or without surgical excision (14, 15). At this juncture, a critical question arises, one that is essential for determining the subsequent approach to patient care. This question stems from the challenge of distinguishing between radiation necrosis and actual tumor growth or progression, a task that often presents a complex diagnostic dilemma. The body of literature addressing this topic is extensive, highlighting the significance of this dichotomy. Indeed, the issue of differenti-

ating between radiation-induced changes and tumor progression is so critical that it warrants being the focal point of an entire research endeavor (16).

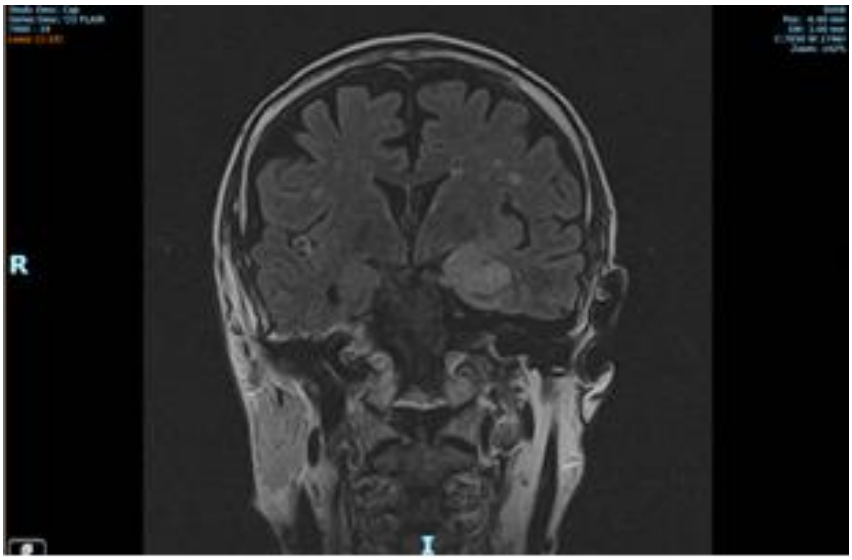

Fig. 4. Coronal FLAIR images of 69M with WHO grade 2 diffuse astrocytoma (Left Temporal Lobe)

CONCLUSIONS

Our examination of existing literature, coupled with a small-scale retrospective study, has provided us with clearer insights into the optimal strategies for addressing the challenging decision of whether and when to surgically intervene in cases of slow-growing low-grade glioma, particularly among relatively young patients exhibiting minimal or no neurological symptoms.

Maximal surgical resection offers not just substantial oncological advantages but also plays a significant role in influencing the epilepsy outcomes for patients diagnosed with diffuse low-grade glioma. A crucial benefit of early and maximally aggressive resection of low-grade tumors lies in the potential for controlling the glioma prior to its progression to a more advanced stage. This approach not only aims to enhance life expectancy but also to improve the quality of life for patients. Furthermore, surgical intervention stands as the sole method for obtaining tumor samples for molecular and histological sub typing, such as determining IDH status. This capability is immensely valuable for more accurately discussing prognoses or tailoring treatment strategies based on the tumor's specific characteristics.

Epilepsy has emerged as a pivotal factor in the intricate and often challenging diagnosis of glioma, serving variously as an early indicator and a quantifiable outcome following surgical resection.

CONFLICT OF INTEREST AND FUNDING

The authors have declared that there are no conflicts of interest in relation to this research, and no funding was secured for the study.

COMPUTED TOMOGRAPHY *VERSUS* PCR TEST: EVALUATING THE DIAGNOSTIC PRECISION OF CHEST COMPUTED TOMOGRAPHY IN COVID-19 PATIENTS (Abstract): The **aim** of the study is to analyze the lesions detected on chest computed-tomography in case of patients with suspicion of COVID-19 infection in comparison with RT-PCR (+), exploring the correlation between demographic factors and disease progression. **Materials and methods:** We retrospectively studied 830 patients suspected to have COVID-19 infection, who underwent computed tomography at "Sf. Spiridon" County Clinical Emergency Hospital, Iasi, Romania, from January to December 2021, and found 108 patients with lung lesions consistent with COVID-19 infection. We explored the correlation between demographic factors and disease progression, established CO -RADS classification and the correlation with PCR test. **Results:** Among 108 patients who had chest CT lesions consistent with COVID-19 infection, 92 patients had a positive RT-PCR test. Our study found a slight male predominance (54.63%), with moderate to severe cases more common among males, and an increased incidence in patients over 50, peaking in the 50-59 age group (33.33%). Severe cases being prevalent in the 60-69 age group (9.26%), suggesting a higher risk in these age ranges. Ground glass opacity was the most common CT finding (96.30%), while less common findings included pericardial effusion and halo signs (2.78%). A significant correlation was observed between CO-RADS classification and disease severity, with 53.70% of the most severe cases associated with CO-RADS 5. These findings suggest that CO-RADS classification helps also in assessing COVID-19 severity. **Conclusions:** Patients above 50 years old have a high risk of developing pulmonary lesions in case of COVID-19 infection; most of the patients with severe course were between 50 and 69 years old suggesting this age range is a risk factor. Ground glass appearance was the most common finding depicted on CT, seen in a majority of the cases, the other findings (pericardial effusion, halo sign and reversed halo sign) being less frequent. In our study the majority of the patients that had positive RT-PCR test, as well as severe disease, had also CO-RADS 5, which may suggest a positive correlation between the CO-RADS classification and the severity and the likelihood of having COVID-19 infection. **Keywords:** COVID-19, COMPUTED-TOMOGRAPHY, PULMONARY LESIONS, PCR.

Human coronavirus was first described in the 1960s (1). It was considered a causative agent for intestinal and upper respiratory tract infection both in animals and humans. However, before the outbreak of severe acute respiratory syndrome (SARS) in 2003 in China, it was not considered to be highly pathogenic to humans (2). Coronavirus belongs to the family of *Coronaviridae*, with the subfamily *Coronavirinae*. This member of the family is known to infect a broad range of hosts, resulting in a disease ranging from the common cold to severe and sometimes even fatal illnesses, such as SARS, MERS and, presently COVID-19(3).

This highly contagious infectious disease caused more that 2.9 million deaths worldwide until to April 2021, becoming the most consequential global health crisis in the world had since the influenza pandemic of 1918 (4). Beside the fact that COVID-19 primarily attacks the respiratory system causing cough, sputum production and shortness of breath (which remain the most common symptoms, followed by fever), it also can affect multiple other organs like the pancreas and induce pancreatic injury (producing acute pancreatitis) or even diabetes mellitus in due time (5, 6, 7).

CT scan aided in establishing the diagnosis and determining the severity of the disease, sometimes pulmonary lesions being visible even before the onset of symptoms. Studies found that ground-glass opacity is the most frequent finding on chest CT in COVID-19 infection, accounting for about 86% of the cases, consolidation (29%), mediastinal lymphadenopathy, nodules, cystic changes, and pleural effusion%; other characteristic pattern of the disease is the presence of bilateral lesions (76%), and mostly with a peripheral distribution (33%) (8,9,10).The evaluation of the lesions and CO-RADS staging can be easier if an artificial intelligence program is used (11).

Most of the times associated diseases like the cardio-vascular conditions (appearing frequently after the age of fifty) and the malignant tumors (which are encountered at any age) aggravate all the symptoms, knowing that the immune system is correlated with infections as well as in cancer (12, 13), Patients with diabetes mellitus have an increased risk of developing infections (14,15,16,17,18). Even though they had no prior history of diabetes, some COVID-19 patients acquired insulin resistance and raised blood glucose levels (14, 16, 19).

MATERIALS AND METHODS

Our retrospective study included 830 patients suspected to have a COVID-19 infection because they presented weakness, fever, and a new cough, and underwent computed tomography at “Sf. Spiridon” County Clinical Emergency Hospital, Iasi, Romania, from January to December 2021. Among the analyzed patients, we discovered 108 with age ranges from 19 to 92 years who had on CT pulmonary lesions consistent with SARS-CoV-2 infection; 92 of them were confirmed to have COVID-19 by positive RT-PCR tests.

The patient's data, including the computed tomography images, were collected from the medical records of Sf. Spiridon, Iasi. The CT scan images were reviewed by a radiologist with over 20 years of experience in the field.

For all patients, we analyzed the following demographic characteristics and CT scan findings: gender, age, location, and pattern of the pulmonary lesions. We established a CO-RADS classification, quanti-

fied the severity of the disease (mild, moderate, and severe) and correlated CT images with PCR test.

Computed tomography findings we considered included lung consolidation, ground glass appearance, halo sign, reversed halo sign, crazy paving, pleural effusion, and pericardial effusion.

The majority of the subjects (98) performed a non-enhanced chest CT, and therefore, no special preparation of the subjects was needed.

RESULTS

We evaluated 108 cases (average age 60.2 years), 59 males (54.63%) and 49 females (45.73%) who presented with chest CT lesions consistent with being determined by COVID-19 infection; among them, 92 patients had a positive RT-PCR test, 6 patients had a negative RT-PCR test, and 10 patients had no RT-PCR test documented (N/A). The patients in the study were divided into groups according to age and gender (tab. I).

TABLE I.

Prevalence of the disease correlated to age and gender

Age group	N	Fr (%)	Male	Fr (%)	Female	Fr (%)
19-29	1	0.93%	0	0.00%	1	0.93%
30-39	5	4.63%	3	2.78%	2	1.85%
40-49	14	12.96%	9	8.33%	5	4.63%
50-59	36	33.33%	20	18.52%	16	14.81%
60-69	25	23.15%	11	10.19%	14	12.96%
70-79	18	16.67%	10	9.26%	8	7.41%
80-89	8	7.41%	5	4.63%	3	2.78%
90-99	1	0.93%	1	0.93%	0	0.00%

RT-PCR results according to gender

Among the male patients, 48 patients (44.44%) had a positive RT-PCR test, 4 patients (3.70%) had a negative RT-PCR test, and 7 (6.48%) patients had no RT-PCR test documented. Among the female patients, 44 (40.74%) patients had a positive RT-PCR test, 2 (1.85%) patients had a negative RT-PCR test, and 3 patients (2.78%) had no RT-PCR test documented.

The disease severity according to the CT findings

The severity of the disease was assessed by examination of the chest CT images, evaluating the extension of pulmonary lesions. Accordingly, the patients were divided into 3 groups of severity: mild (30%), moderate (60%), and severe (more than 60%). In some patients, the severity could not be assessed (N/A). 27 patients (25.00%) had mild disease, 29 patients (26.85%) had moderate disease, and 32 patients (29.63%) had severe disease. In 20 patients (18.52%), the severity could not be assessed (N/A). In table II, we summarized the relationship between disease severity and age.

The severity of the disease in relation to the gender of the patients

Analyzing the severity of the disease for each gender revealed that only in cases of mild severity did we encounter more fe-

males (M/F = 10/17 patients); instead, when counting the moderate and severe cases, there were more males involved (M/F = 35/26) (tab. III).

TABLE II.

Disease severity according to the age groups

Age group	Mild N	Mild %	Moderate N	Moderate %	Severe N	Severe N	N/A-N	N/A %
19-29	0	0.00%	0	0.00%	0	0.00%	1	0.93%
30-39	1	0.93%	1	0.93%	2	1.85%	1	0.93%
40-49	6	5.56%	4	3.70%	3	2.78%	1	0.93%
50-59	10	9.26%	12	11.11%	9	8.33%	5	4.63%
60-69	5	4.63%	6	5.56%	10	9.26%	4	3.70%
70-79	3	2.78%	5	4.63%	7	6.48%	3	2.78%
80-89	2	1.85%	0	0.00%	1	0.93%	5	4.63%
90-99	0	0.00%	1	0.93%	0	0.00%	0	0.00%

TABLE III.

Correlation between the severity of the disease and the gender of the patient

Severity	M (n)	Male %	F (n)	Female %
Mild	10	9.26%	17	15.74%
Moderate	17	15.74%	12	11.11%
Severe	18	16.67%	14	12.96%
N/A	14	12.96%	6	5.56%

The pattern of the disease

CT describes the pattern of the lung lesions (ground glass lesions, pulmonary consolidation, reversal halo sign, halo sign, crazy paving) and the associated lesions pleural, and pericardial spaces (pleural effusion, pericardial effusion). The dominant lesion found was the ground glass opacity, present in 104 patients' CT (96.30%), and the second lesion was consolidation (38 patients, 35.19%). Other lesions in descending order are pleural effusion (13 patients (12.04%)), crazy paving (6 patients (5.56%), pericardial effusion, halo sign pattern, and reversal halo sign pattern, which were seen only in 3 patients for each of them (2.78%).

GGO being the dominant lesion seen on CT scans, all the other lesions found were combined with the ground glass appearance (fig. 1):

- 38 patients (35.19%) also had pulmonary consolidation, while the rest, 66 patients (61.11%), had no consolidation.

- 13 patients (12.04%) also had pleural effusion, while 91 patients (84.26%) with a ground glass appearance had no pleural effusion.

- 6 patients (5.56%) also had crazy paving, while 98 patients (90.74%) with a ground glass appearance had no crazy paving.

- 3 patients (2.78%) also had pericardial effusion, a reversed halo sign, and a halo

sign, respectively, while 101 patients (93.52%) with a ground glass appearance did not have such lesions.

CO-RADS classification

The COVID-19 Reporting and Data System (CO-RADS) is a computerized tomography (CT)-based system that assesses the suspicion of lung involvement in COVID-19 pneumonia patients. It should be noted that the confirmation of COVID-19 depends on an RT-PCR test. The CO-RADS classification provides a degree of suspicion for pulmonary involvement depending on the findings seen on a non-contrast enhanced chest CT. The grades range from very low (CO-RADS 1) to very high (CO-RADS 5). In addition, technically insufficient examination is stated as CO-RADS 0, and RT-PCR-proven SARS-CoV-2 infection is stated as CO-RADS 6.

In our study, applying the patients' CO-RADS classification revealed results ranging from CO-RADS 1 to CO-RADS 5. Most of them (58 patients, or 53.70%) had chest CT findings correlated with CO-RADS 5 (fig. 2).

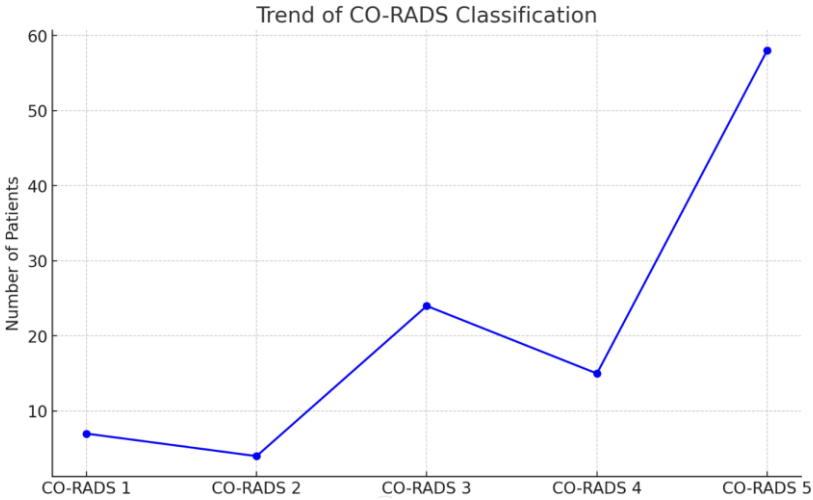

Fig. 2. Line chart illustrates the trend of patient numbers across different CO-RADS classifications

All the patients with CO-RADS 1 and CO-RADS 2 had positive RT-PCR tests. Most of the patients with CO-RADS 3, 4, and 5 had positive RT-PCR tests (23 pa-

tients, 16 patients, and 53 patients, respectively). One patient with CO-RADS 3, one from the group of CO-RADS 4, and six patients with CO-RADS 5 had a negative RT-PCR test. The correlation between CO-RADS score and RT-PCR test results are summarized in tab. IV.

The correlation between CO-RADS score and the severity of the disease

Among the 58 patients with a CO-RADS score of 5, 11 patients (10.19%) had mild disease, 19 patients (17.59%) had moderate disease, and 28 patients (25.93%) had severe disease (tab. V).

TABLE IV.

Summarize CO-RADS score in correlation with the RT-PCR test results

CO-RADS score	n	Freq (%)	Positive RT-PCR	Freq (%)	Negative RT-PCR	Freq (%)	Without RT-PCR test	Freq (%)
1	7	6.48%	2	1.85%	0	0.00%	5	4.63%
2	4	3.70%	2	1.85%	0	0.00%	2	1.85%
3	24	22.22%	19	17.59%	2	1.85%	3	2.78%
4	15	13.89%	14	12.96%	1	0.93%	0	0.00%
5	58	53.70%	55	50.93%	3	2.78%	0	0.00%

TABLE V.

CO-RADS score in correlation with the severity of the disease

CO-RADS score	1	2	3	4	5

N/A	7	4	9	0	0
Freq (%)	6.48%	3.70%	8.33 %	0%	0%

DISCUSSION

The patients' age appears to play an important role, with a clear peak in the age group 50-59, which included 36(33.33%) patients. Studying the relationship between age and the severity of the disease shows that the majority of patients with severe disease are between 50 and 79 years old (26 patients from a total of 32 patients with severe disease), with only 1 patient with severe disease above 80 years old and 4 patients below 50 years old. The age groups 30-39, 50-59, and 70-79 included patients with the three levels of severity, and the distribution of the patients between the levels of severity was almost equal

without a predominant course. While the age group 40-49 had a peak of mild course, the age group 70-79 had a peak of severe course.

The study found a slight male predominance (54.63%), with moderate to severe cases more common among males, whom according to previous studies are considered a risk group. With regard to the severity of the disease in relation to gender, there is a little increase in the severe and moderate cases among the male gender, with 18 male patients (16.67%) versus 14 female patients (12.96%) in the severe course and 17 male patients versus 12 female patients in the moderate course. Furthermore, in the mild course, there is a small peak in the female gender when compared to the male gender, with 17 female patients, representing 15.74% of the total patients, and 10 male patients, representing 9.26% of the total patients.

Evaluating CT scan images in order to determine diseases' severity, we didn't depict notable differences among the three categories: mild, moderate, and severe disease, which represented 27 (25%), 29 (26.85%), and 32 patients (29.63%), respectively, but we also had 20 (18.52%), for whom the severity could not be assessed.

GGO was the most dominant lesion involving the lungs, appearing in 104 patients out of the total 108 patients. The second dominant lesion is pulmonary consolidation, which appears in 38 patients. Next was pleural effusion, seen in 13 patients; a crazy paving pattern was seen in 6 patients; while the other lesions - pericardial effusion, reversal halo sign, and halo sign-were seen in only 3 patients each.

Most of the patients had CO-RADS 5, accounting for 58 (53.7%) from the total 108 patients. The majority of the patients with CO-RADS 5 had positive RT-PCR tests and are 55 in number out of a total of 92 patients with positive RT-PCR tests.

CONCLUSIONS

COVID-19 infection has a slight prevalence among the male gender, most of the patients with moderate and severe courses are males, while the majority of the patients with mild courses are female.

There is a higher incidence in patients above 50 years, and a severe disease appeared above 60 years old, confirming that these age ranges are a risk factor.

Ground glass appearance was the most common finding seen in the CT scan of these patients, seen in a majority of the cases. Less common findings were pericardial effusion, the halo sign, and the reversed halo sign. Our findings show that the majority of the patients who had positive RT-PCR tests as well as severe disease also had CO-RADS 5, which may suggest a positive correlation between the CO-RADS classification, disease severity, and likelihood of having a COVID-19 infection.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research

ADDITIONAL INFORMATION

Patient consent was obtained for presenting this case in a medical publication to contribute to the expansion of the database on this pathology.

The ethics committee of the medical unit has approved the presentation of the case in a medical article in a medical publication while respecting personal data.

UNVEILING THE IMPACT OF INTRAUTERINE ADHESIONS ON INFERTILITY: A COMPARATIVE JOURNEY THROUGH PRIMARY AND SECONDARY INFERTILITY PATIENTS (Abstract): Intrauterine adhesions (IUAs) represent an important cause of infertility, having various effect in patients with primary and secondary infertility. The objective of the study is to evaluates the clinical, demographic, and intraoperative characteristics of patients with IUAs, focusing the correlation between hysteroscopic and laparoscopic tubal patency assessment and infertility type. **Materials and methods:** A retrospective descriptive study was conducted between 2016 and 2024 at two hospitals in Iasi, Romania: Clinical Hospital of Obstetrics and Gynecology "Elena Doamna" and "Cuza-Vodă". Medical records identified 134 patients with IUAs, of whom only 102 patients met the inclusion criteria and divided in two groups: primary and secondary cohorts. All patients underwent hysteroscopic adhesiolysis to restore the anatomy of uterine cavity, with perioperative tubal patency evaluation and confirmed laparoscopically in most cases. **Results:** Patients with IUAs and primary infertility were younger (31.66 *vs.* 34.13 years; p=0.023) and predominantly aged 25-34 years, whereas IUAs patients and secondary infertility was more common in those over 35 years. Secondary infertility subjects showed higher rates of repetitive dilation and curettage (77%, p=0.001), ectopic pregnancies (6.6%, p=0.04). Hysteroscopic and laparoscopic tubal patency revealed a higher patency rate in secondary infertility cases (90.2%) compared to primary infertility cases (73.2%, p=0.038). Bilateral positive patency through the laparoscopic Dye test was more common in primary infertility cases (61% *vs.* 41%, p=0.029). This study highlights distinct clinical and intraoperative characteristics between primary and secondary infertility in patients with AIUs. Secondary infertility was significantly associated with higher rates of previous D&Cs, increased hysteroscopic and laparoscopic tubal patency rates and ectopic pregnancies. **Conclusions:** This study emphasize the importance of tailored diagnostic and therapeutic approaches to optimize outcomes for patients with IUAs and infertility. **Keywords:** INTRAUTERINE ADHESIONS, HYSTEROSCOPY, HYSTEROSCOPIC ADHESIOLYSIS, LAPAROSCOPY, TUBAL PATENCY, INFERTILITY, ENDOMETRIAL RECEPTIVITY.

INTRODUCTION

The endometrium represents the internal layer of the uterus that is highly specialized for embryo implantation and sensitive to hormonal synthesis during the endometrial cycle. Ovarian hormones are essential for endometrial changes. If a pregnancy occurs during the window of implantation, the intrauterine microenvironment suffers specific changes due to progesterone secretion during the secretory phase to become more receptive for the implantation (1, 2). Numerous growth factors such as vascular endothelial growth factor (VEGF) and insulin-like growth factor are involved in the secretory phase, establishing changes in the proliferative endometrium, to become better vascularized and to remodel the maternal spiral arteries in order to decrease the vascular resistance and to increase the uteroplacental blood flow. The interplay between embryo and immune system is complex. The natural killer cells, cytokines and chemokines presents autocrine or paracrine properties and modulates the immune interaction in between to protect both the mother and the embryo but also to limit the trophoblastic invasion for a favorable implantation (3, 4) Modulatory factors like interleukin-10 (IL-10) and transforming growth factor-beta (TGF-beta) regulates the proliferation, migration and trophoblastic invasion and poses antiproliferative signals at the level of the uteroplacental interface to create a tolerant microenvironment. Genetic factors play an important role in endometrial repair conditions. Multiple genes and proteins have been implicated in cellular adhesion process and endometrial remodeling when pregnancy occur. Endocrine, neuronal, metabolic, immunologic, and mechanic factors harmonize together to develop the fertilized egg into a blastocyst and later to become an embryo but also, to establish a mature endometrium that allows proper implantation and following advance of early pregnancy (1, 2, 3).

The mechanisms by which the intrauterine adhesions (IUAs) affect the implantation of a pregnancy are not fully understood nor the factors implicated in its pathogeny. The precise process underlying modifications in endometrial repair is poorly knew. Understanding the molecular and cellular mechanisms activated following intrauterine surgery or trauma which are engaged in the endometrium regenerative pathways is essential since are playing a key role in endometrial receptivity, fertility or pregnancy complications (2). The effect of a mechanical trauma or an infectious process at the level of the endometrial basal layer may lead to blastocyst implantation failure, lessen of feto-uterine blood flow near the beginning or recurrent miscarriages. Intrauterine adhesions appear due to a disproportionate limited healing course that determines the rise of fibrous, thin or dense strips between the uterine walls which can induce partial or full obliteration of endometrial cavity or / and cervical canal.

The incidence and prevalence vary among population studied or geographic areas; The real incidence of IUAs is actually undetermined due to a sizeable number of cases that lack of symptoms or patient's neglection; besides, the paucity of diagnosis tools decreases the diagnosis rate in different geographic areas (5).

Any method of endometrial injury can be a cause for intrauterine adhesion formation. The etiology is multifactorial but the uterine curettage for different pathologies like miscarriage, abortion, postpartum placental fragments retention or curettage in non-pregnant patients are the most im-

plicated (6, 7, 8, 9). Others may be caesarean section, B-lynch suture, Bakri balloon application, hysterotomies, hysteroscopic surgery (10, 11), due to mechanical trauma of the endometrial tissue, uterine artery embolization for leiomyoma, endometritis or pelvic inflammation (4, 5, 12). The mechanical factors explain how intrauterine adhesions can affect the remodeling and maturation of the endometrium during the secretory phase. The damage of cellular elasticity and cytoskeletal architecture of the basal layer, resulting in endometrial fibrosis or adhesions formation, influence the adequate vascular reorganization, an essential stage for trophoblastic invasion. Genetic factors play an important role in endometrial repair conditions.

The objective of the study is to analyses the clinical and demographic characteristics, patient's history, and intraoperative findings in individuals with IUAs and infertility, aiming to summaries the etiology and risk factors and to identify features that influence diagnosis, management, and reproductive outcomes. A secondary objective is to corelate the hysteroscopic and laparoscopic tubal patency, attempting to set the best therapeutic approach for these patients considering future fertility.

MATERIALS AND METHODS

We conducted a retrospective study, during a 9-year period, between 2016-2024 in two hospitals, "Elena Doamna" Clinical Hospital of Obstetrics and Gynecology and "Cuza-Vodă" Clinical Hospital of Obstetrics and Gynecology from Iasi, Romania.

The patient's medical data was collected from the medical sheet and reviewed with the medical history of the subjects. The primary selection of cases included 134 patients diagnosed with intrauterine adhesions of which only 102 patients associated infertility and were elected for the study. The study group was later divided in two study cohorts according to the type of infertility, primary or secondary. Other inclusion criteria are: patients that provided an informed consent with age between 18-45 years and hysteroscopic diagnosis of intrauterine adhesion. The exclusion criteria were applicable in cases with unsigned consent, and incomplete follow-up. The study adhered to the principles of the Declaration of Helsinki and received ethical approval from the committees of the participating hospitals, "Elena Doamna" Clinical Hospital of Obstetrics and Gynecology and "Cuza-Vodă" Clinical Hospital of Obstetrics and Gynecology from Iasi, Romania.

The study was approved by the Hospital Institutional Review Board of both Clinical Hospitals "Elena Doamna" (approval no. 389/13.01.2023) and "Cuza-Vodă" (approval no. 13.881/15.12.2020), as well as from the Ethics Committee of ''Grigore T. Popa'' University of Medicine and Pharmacy Iasi (approval no. 402/15.02.2024). The study's design and data management conformed to both national and international guidelines for human participant research.

In all cases hysteroscopic adhesiolysis was performed to reestablish the anatomy of uterine cavity (13). During the hysteroscopy, a perioperative tubal evaluation was performed, considering the ''air bubble technique'' assessment. The hysteroscopic tubal patency was confirmed by the laparoscopic tubal patency test using blue methylene in almost all cases (5).

The statistical analysis used *SPSS* software, version 18.0 and, at first, data were arranged and summed up for interpretation; after that an analysis was made to deduce

supplementary indicators using comparative statistical approaches. To postulate the statistical results in our study, a representative specimen size of women from Iasi population was elected (n=394,274) and calculated, conceding an estimated sample of 136 persons, with an 8.4% sampling miscalculation. The limits of error arrange nearly with the values found in the literature, and the specimen size selected resembles with the number of patients selected from the two hospitals from Iasi, in 2024.

RESULTS

The distribution of age among included patients is homogeneous, with mean and median values closely aligned (33.14 *vs.* 33 years), and a Skewness test result of 0.039, indicating suitability for applying significance tests to continuous variables (fig. 1).

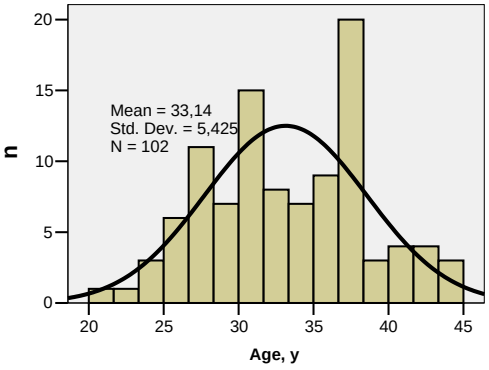

Fig. 1. The histogram of patient's age diagnosed with intrauterine adhesions and infertility

The average age was marginally lower among patients with primary infertility (31.66 compared to 34.13 years; p=0.023), with an age range of 21 to 45 years (Fig. 2). In terms of accessibility within the analyzed group for specialized medical services, a higher rate of 61.8% of the patients originated from urban areas compared with the rural area, but were found no statistically significant differences regarding the infertility type: 56.1% of patients had primary infertility, and 65.6% has secondary infertility (p=0.335).

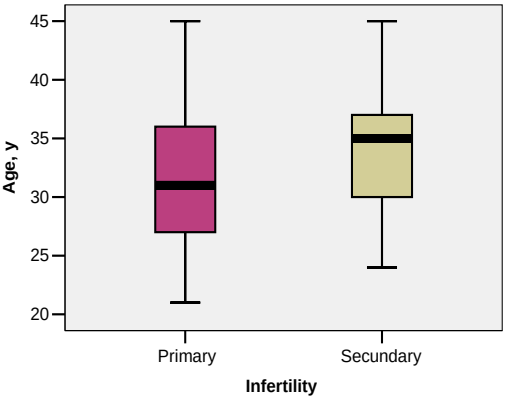

Fig. 2. Comparative mean age across study groups: primary and secondary infertility

Patients with primary infertility were most commonly identified within the 25-34 age group (61%), whereas the ones diagnosed with secondary infertility were mostly encountered among individuals aged over 35 years (50.8%). Preoperative diagnosis supposition according to clinical symptoms was observed in 17.3% of all primary infertility cases and 61% of patients with secondary infertility (p=0.001). Ultrasonographic diagnosis, using transvaginal two-dimensional ultrasonography (2D-US) or three-dimensional ultrasonography (3D-US) was established in 26.9% of patients with primary infertility and 68.3% of those with secondary infertility (14, 15, 16). Among patients diagnosed with intrauterine adhesions and secondary infertility, 32.8% had a history of more than two dilation and curettage (D&C) procedures (p=0.001) (tab. I).

Gynecological history revealed no statistically significant differences in the prevalence of intrauterine adhesions between types of infertility (p>0.05). Still, in patients with IUA and secondary infertility, the D&C (77%, p=0.001) and caesarean section (21.3%; p=0.001) were performed with significantly higher frequency (17) (tabs. I, II).

TABLE I.

The structure of infertility cases based on obstetrical history

Obstetrical history	Primary infertility		Secondary infertility		Chi square test
	No.	%	No.	%

The American Fertility Score (AFS) system for intrauterine adhesions was used to correlate the cases of intrauterine adhesion and infertility. A higher number of D&C was significantly associated with AFS stage 2 (tab. III) (17).

TABLE III.

The correlation between the AFS stage and the number of uterine curettages

Bilateral negative patent TO	5	12.2	1	1.6	
History of ectopic pregnancy	0	0.0	4	6.6	0.040

TO= Tubal ostia

The hysteroscopic perioperative tubal assessment indicated that patient's fallopian tubes were largely patent, when using the "air bubble" technique, with tubal ostia showing a predominant patency rate of 73.2% in primary infertility cases compared to 90.2% in secondary infertility cases (p=0.038) (5). The hysteroscopic tubal patency was confirmed by the laparoscopic tubal patency test in most cases, using blue methylene. In all cases of IUAs with primary infertility the tubal patency was evaluated via dye diffusion with methylene blue during the laparoscopic surgery. In comparison, tubal patency assessment was conducted in 98.4% of patients with secondary infertility.

Bilateral positive tubal patency was most frequently observed though the laparoscopic Dye test, with rates of 61% in primary infertility cases compared to 41% in secondary infertility cases (p=0.029). Still, ectopic pregnancy was identified only in 4 cases (6.6%; p=0.04) within patients with secondary infertility (tab. IV).

DISCUSSION

Patients diagnosed with IUAs who undergo hysteroscopic adhesiolysis exhibit an increased risk of infertility and complications during pregnancy. The elevate rate of infertility observed in this population are likely associated with diminished endometrial receptivity. This downturn of endometrial receptivity may result from damage to the basal layer of the endometrium mucosae or from the recurrence of the IUAs following adhesiolysis. However, the precise mechanisms underlying these outcomes remain incompletely understood. The incidence of IUAs varies based on the demographic area studied and the etiology beyond.

Among a cohort of 102 patients with IUA, a significant difference in mean age was identified between those with primary infertility and those with secondary infertility. Specifically, patients with primary infertility had a mean age of 31.66 years, compared to 34.13 years in the secondary infertility group (p=0.023). Compared to existing literature, the mean age in both groups in this study was slightly lower than previously reported averages from other studies (18).

These findings emphasize the evidence that IUA may represent a potential risk factor for infertility and pregnancy complications. The observed age disparity between two groups noticed in our study is particularly noteworthy as may reflect the earlier clinical presentation and diagnosis of IUA with primary infertility (18). Furthermore, the influence of geographic and etiologic factors in the incidence of IUA sustain the IUA pathology. In out study, the higher proportion of patients from urban areas compared to rural areas indicate that better accessibility to healthcare, diagnostic devices and management options in urban regions facilitates earlier detection and treatment options. The lower incidence of our groups compared with other geographic areas with lessen access to medical assistance from the literature can be interpreted as requirement for area-specific prophylactic programs for IUA and infertility (11).

The notable difference in the preoperative diagnosis based on clinical symptoms between patients with primary and secondary infertility (17.3% *vs.* 61%, p=0.001) aligns with the earlier studies that secondary infertility is more likely to involve identifiable risk factors, such as previous intrauterine surgeries, which could prompt clinical suspicion of IUAs (2). Two-dimensional (2D) and three-dimensional (3D) transvaginal ultrasonography (US) aligns with the general understanding, revealing an increased diagnosis rate for IUAs in secondary infertility group (68.3%) compared to primary infertility group (26.9%) (10).

The incidence of dilation and curettage (D&C) confirmed the already known risk factor for IUAs developing. In patients with IUAs and secondary infertility, D&C and caesarean section were frequently performed (77%, p=0.001 as well as 21.3%, p=0.001) which suggests a greater like hood of these procedures for secondary infertility patients and can explain the elevated prevalence of IUAs observed in this group. These results emphasize the literature findings about IUAs development which suggest that a history of uterine trauma through surgical interventions plays a decisive role in the IUAs pathogenesis and impacts reproductive performance. The correlation of AFS system stage 2 and repeated D&C among secondary infertility group reveals how repeated mechanical trauma impacts the IUAs constitution, but also a possible cumulative effect. The repetitive D&C procedures correlate with a severe IUAs or Asherman syndrome as the literature showed already, this article highlights the idea that a prudent and minimal invasive management of intrauterine procedures or surgeries is crucial for to preserve uterine anatomy and function, and further, the fertility potential of the patient (10, 19).

The differences towards tubal patency assessment between primary and secondary patients with IUAs reiterate other studies which suggested that secondary infertility is more frequent correlated with partial or maintained fallopian tubes function even when the IUAs are associated. Our study showed an increase rate of bilateral tubal patency indicating that tubal functionality may be preserved in this group even though IUAs are associated. Moreover, these findings propose that the primary cause of infertility in these patients is rather related to endometrial receptivity disruption than corelated to tubal dysfunctionality. On the other hand, the decrease tubal patency rate found within secondary infertility group can correlate with an increase incidence of anterior uterine interventions or infections that can cause partial tubal occlusion or localized tubal damage. Moreover, the ectopic pregnancies found within the secondary infertility group highlight the feasible impact of IUAs and other prior uterine

interventions or infections which may cause damage of tubal function.

Using hysteroscopy simultaneously, in the same operative time with the laparoscopy for tubal patency appraisal in infertility patients highlights the weight of an inclusive management based on the infertility type but further studies need to investigate the prognostic value of these two methods together for tubal patency diagnostic and their impact on reproductive performance in IUAs patients. Currently, there are new challenges in the treatment of endometrial pathology, involving innovative approaches and opening new perspectives that can impact both the quality of life and patients' response to infertility (20-23).

CONCLUSIONS

Patients with IUAs and primary infertility are more likely to be associated with endometrial or implantation factors, while secondary infertility often involves tubal compromise influenced by prior interventions. The surgical history has a crucial role in the development and progression of IUA, as well as its impact on tubal patency and overall fertility outcomes. The integration of hysteroscopic and laparoscopic evaluations proved essential for accuracy diagnosing IUAs and assessing tubal function helping to individualize the treatment and reducing the risk like ectopic pregnancies, especially in patients with secondary infertility.

ACKNOWLEDGEMENTS

The authors express their profound gratitude to the "Elena-Doamna" Clinical Hospital of Obstetrics and Gynecology and "Cuza-Vodă" Clinical Hospital of Obstetrics and Gynecology from Iasi, Romania, for providing the necessary infrastructure and access to medical records for this research. Acknowledgment is also extended to the "Grigore T. Popa" University of Medicine and Pharmacy, Iasi, for supporting Ph.D. candidate Himiniuc (Toma) Loredana Maria through the founding of a doctoral grant. The invaluable assistance of the medical staff in patient data collection and analysis is deeply appreciated.

CONFLICT OF INTERESTS

The authors declare that there are no conflicts of interest related to the publication of this article.

BREAST NEOPLASM IN PATIENTS WITH PULMONARY THROMBOEMBOLISM: A RETROSPECTIVE STUDY (Abstract): This study **aims** to evaluate the incidence of pulmonary embolism among breast cancer patients, emphasizing its correlation with the histological types, cancer staging, and thrombus characteristics **Materials and methods:** We retrospectively analyzed 211 patients diagnosed with pulmonary thromboembolism (PTE) using contrast-enhanced chest computed tomography at "Sf. Spiridon" County Clinical Emergency Hospital, Iasi, from the 1st of January 2023 to 31st of November 2024. Patients with previous diagnosis of breast cancer were identified, and data including demographic details, breast cancer stage, histopathological findings, and thrombus localization were collected. **Results:** The incidence of breast cancer associated with PTE, found in our cohort was 4.73% (n=10), with a majority of postmenopausal women (80%), a median age of 55 ± 6.96 years and an interquartile range (IQR) of 9.25 years. Incidence by cancer stage was as follows: stage I -0.47 % (n=1), stage II - 0.94% (n=2), stage III - 0.94% (n=2), stage IV - 2.36% (n=5). The incidence was higher among patients with stage IV cancer (2.47%) compared to stage I-III (0.5-1%). Histologically, 9 patients (4.26%) were diagnosed with invasive ductal carcinoma (IDC), while only 1 patient (0.47%) had invasive lobular carcinoma (ILC). Studying thrombus localization we found saddle thrombus in one case (0.47 %), lobar artery thrombi in 2 cases (0.94 %) and 7 patients (3.31 %) with segmental and subsegmental arteries thrombosis. None of the patients had PTE preceding breast cancer diagnosis, all PTE occurred after treatment, with acute PTE being found in 2 cases - 0.94%, while the other 8 (3.79%) were diagnosed as chronic thrombosis **Conclusions**: Pulmonary thromboembolism was observed in 4.73% of breast cancer patients, with a majority of postmenopausal women, a higher prevalence in patients with advanced-stage disease, all PTE occurring after treatment, most of them being chronic thrombosis. The study's limitations include a small study group and study duration. **Keywords:** PULMONARY THROMBOEMBOLISM, BREAST CANCER, COMPUTED TOMOGRAPHY, MALIGNANCY-ASSOCIATED THROMBOSIS.

INTRODUCTION

Breast cancer is the most frequently diagnosed malignancy in women worldwide and the leading cause of cancer-related mortality in females, according to World Health Organization (WHO) (1). Given its high prevalence, the correlation between breast cancer and thromboembolic events, such as PTE, has become a significant clinical concern (2).

PTE is a life-threatening complication and a major cause of morbidity and mortality, with an annual incidence of 39-115 cases per 100,000 individuals (3). PTE is frequently associated with malignancy, particularly due to cancer-induced hypercoagulability and cancer-related treatments, which increase thromboembolic risk by four to seven times compared to the general population (2, 4, 5).

Certain malignancies, such as pancreatic, ovarian, brain, stomach, gynecological, and hematological cancers, carry a high risk for thromboembolism, while lung and colorectal cancers pose an intermediate risk. Breast cancer is traditionally considered to have a lower risk of thromboembolism than these malignancies; however, literature on this topic remains limited (2, 6).

Imaging plays an important role in the evaluation and management of PTE and contrast-enhanced chest computed tomography remains the golden standard for diagnosis (7, 8).

MATERIALS AND METHODS

We conducted a retrospective study using electronic medical records from "Sf. Spiridon" County Clinical Emergency Hospital from Iasi, database analysing patients from the1st of January 2023 to 31st of November 2024, and selected a number of 211 patients diagnosed with PTE. Patients were included in this study if they had histologically confirmed breast cancer and were diagnosed with PTE through contrast enhanced chest computed tomography. SPSS version 29.0 was the software for the statistical analysis. We used descriptive statistics to calculate mean, standard deviation, median, and interquartile range.

Computed tomography pulmonary angiography (CTPA) was performed with a Philips Incisive 64 detector CT with the following protocol: cranio-caudal thoracic scan from the chest aperture to the costophrenic angles, in post inspiratory apnea, beginning with a noncontrast enhanced scan; bolus tracking technique; up to 100 mL (1 mL/kg body weight) iodinated contrast medium (concentration of 370-400 mg iodine/mL) is injected intravenously with an automatic injector, with the speed of 3-4 mL/second (s), followed by 50 mL of saline chaser with the same speed. The delay for the arterial phase scan is 7s after the density in the pulmonary artery reaches 180 HU (Hounsfield Units) and the venous phase is performed at 20 s after the arterial phase (9).

RESULTS

This study aims to provide an in-depth analysis of the correlation between breast cancer and pulmonary thromboembolism through a retrospective observational study. We conducted a retrospective study using electronic medical records from hospital database analyzing patients from the 1st of January 2023 to 31st of November 2024, and selected a number of 211 patients diagnosed with PTE; among them 34 have previously been diagnosed with malignancies, 19 with digestive malignant tumors, 10 with breast cancer and 5 with lung cancer. The incidence of breast cancer associated with PTE found in our study was

4.73% (n=10), less frequently associated with PTE compared to digestive cancers (n=19, 9%) and more frequently compared to lung cancer (2.36%). Among the patients diagnosed with breast cancer, 80% (n=7), were postmenopausal women, while premenopausal women were 20% (n=3). The mean age was 55**,** with standard deviation (SD) 6.96 years and an interquartile range (IQR) of 9.25 years.

The breast cancer stage analysis in our study group was as follows: stage I - 0.47 % (n=1), stage II - 0.94% (n=2), stage III - 0.94% (n=2), stage IV - 2.36% (n=5). This data indicates a higher prevalence of pulmonary embolism among stage IV breast cancer patients (2.36%) compared to those in earlier stages (0.5-1%) (fig. 1).

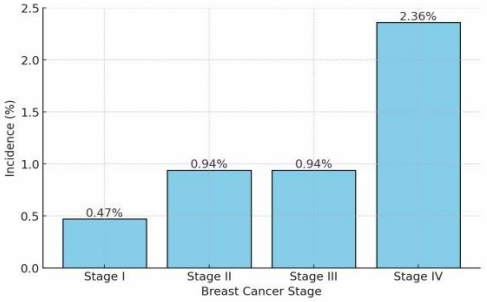

Fig. 1. Breast cancer associated with PTE - stage analysis

Among breast cancer cases, 9 patients (4.26%) were morpho pathologically diagnosed with IDC, while only 1 patient (0.47%) had ILC; these findings are probably related to the frequency of IDC versus ILC, not with the higher tendency of the first type of cancer to be related with PTE (10, 11).

From the perspective of thrombus localization, we found saddle thrombus in one case (0.47 %), lobar artery thrombi in 2 cases (0.94 %) and 7 patients (3.31 %) with segmental and subsegmental artery thrombosis (fig. 2).

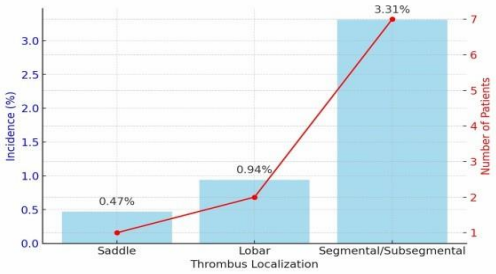

Fig. 2. Breast cancer associated with PTE - thrombus localization

The most important comorbidities in the breast cancer study group were obesity (n=7, 3.31%), heart conditions including ischemic heart disease (n=5, 2.36 %), diabetes (n=2, 0.94%) vasculitis and deep vein thrombosis in the lower limb (n=1, 0.47%) (12, 13).

None of the patients had PTE preceding breast cancer diagnosis, all cases of PTE occurred after treatment, acute PTE was found in 2 cases - 0.94% (the saddle thrombus and one of the lobar artery thrombosis), the other 8 (3.79%) being chronic thrombosis. Considering these two findings we can assume that the thromboembolic risk associated with breast cancer is not necessarily connected to cancer-induced hypercoagulability but rather with cardio-vascular risk factors and cancer-related treatments (14).

DISCUSSION

Our findings align with existing literature indicating that malignancy-associated thrombosis is a well-recognized complication (2, 5, 15). The observed 4.73% incidence of breast cancer patients associated with PTE falls within the range of reported data in the literature for malignancy-associated thrombosis (0.13%-8.65%) which

is higher compared with the incidence of PTE in patients without malignancies (0.11%) (16, 17, 18). PTE incidence that we found is in the middle of the literature range probably because malignancy was found to be associated with PTE particularly in men (4, 19, 20, 21, 22, 23, 24) and our study was exclusively comprised of women.

Moreover, although breast cancer is the number one malignancy in women according to WHO, in our study, digestive cancers (n=19, 9%) were found to be more frequently associated with PTE compared to breast cancers (n=10, 4.73%) This could be attributed to factors such as delayed detection, aggressive tumor type, and distinct thrombotic mechanisms involved in gastrointestinal malignancies.

The most frequent comorbidity in this breast cancer study group was obesity (7 cases) associated in 2 cases with diabetes, both diseases being related to heart conditions and deep vein thrombosis which are associated with a high risk of PTE even without the presence of malignancy and cancer-related treatments (25).

This study is subject to certain limitations, including a relatively small number of breast cancer patients diagnosed with pulmonary embolism, from a single center point of view and a short study duration (two years), which may not fully capture long-term trends and potential biases related to retrospective data collection.

While promising, further validation with a larger cohort and additional predictive variables is required to improve specificity and clinical applicability for PTE in breast cancer patients.

CONCLUSIONS

This retrospective study highlights the notable incidence of 4.73% of PTE in breast cancer patients, with a majority of postmenopausal women, a higher prevalence in patients with advanced-stage disease, all PTE occurring after treatment, most of them being chronic thrombosis. The study's limitations include a small study group and study duration. While breast cancer remains a leading malignancy in women, its association with thromboembolic events needs further research and increased clinical awareness. Future studies with larger sample sizes and multi-institutional data may provide deeper insights into the pathophysiology, and management of breast cancer-associated PTE.

MEDICINAL LEECH THERAPY IN DIGITAL REPLANTATION **(**Abstract): Venous congestion represent a complication in reconstructive microsurgery, particularly in digital replantation and revascularization procedures, where achieving venous outflow may be technically impossible. In these cases, medicinal leech therapy (MLT) offers a biologically active method to decompress congested tissues and improve tissue survival. **Material and methods:** The study included a group of 35 patients that was used treated with MLT for venous congestion following digital replantation. Key variables included timing of therapy initiation, treatment duration, leech application frequency, complications, and salvage outcomes**.** Additionally, we conducted a systematic literature search in PubMed, Scopus, and Google Scholar for studies published between January 2014 and March 2024. Following PRISMA guidelines, we included case reports, series, and clinical studies reporting MLT use in digital replantation or revascularization. **Results:** Our cohort achieved an overall tissue salvage rate of 88.6% (31 of 35 cases), with four failures due to arterial injury. From 134 identified records, 10 studies met inclusion criteria. In the literature, MLT was started within 24-48 hours of congestion onset, lasting 4-7 days, with 2-5 leeches applied daily at 2-4-hour intervals. Reported salvage rates ranged from 66% to 85%. Complications included *Aeromonas hydrophila* infections and anemia requiring transfusion. **Conclusions:** MLT remains an effective, evidence-supported adjunct for venous congestion management after digital replantation, particularly when venous anastomoses are not feasible. A standardized protocol based on recent data may improve outcomes and safety in microsurgery. **Keywords:** VENOUS CONGESTION, DIGITAL REPLANTATION, MEDICINAL LEECH THERAPY, MICRO-SURGERY.

INTRODUCTION

Venous congestion is a common and potentially devastating complication in microsurgery and reconstructive surgery. It arises when venous outflow from a transferred or reattached tissue segment is insufficient, leading to blood stasis, tissue edema, increased interstitial pressure, and ultimately ischemic necrosis. This scenario is frequently in digital replantation. While arterial inflow can typically be reestablished through microsurgical techniques, venous outflow remains more technically challenging-especially in cases with small-caliber veins, avulsion or crush injuries, or irradiated recipient beds. Although microsurgical venous anastomoses are the gold standard, they are not always feasible due

to anatomical or intraoperative limitations, such as thrombosis (1). In such high-risk cases, medicinal leech therapy (MLT) has reemerged as a valuable, biologically active adjunct. Reintroduced into modern clinical practice in the 1980s by Foucher *et al.* for digital replantation, MLT has since been used in various reconstructive procedures at risk for venous congestion (2). Leeches (*Hirudo medicinalis*) relieve congestion through both mechanical blood extraction and biochemical effects from their saliva, which contains hirudin, calin, vasodilators, and anti-inflammatory agents (2). These promote sustained bleeding, prevent clotting, and enhance microcirculation. Despite growing evidence of its efficacy-reporting salvage rates of 70% to 85%-MLT remains underutilized, partly due to concerns over infection (notably *Aeromonas hydrophila*), labor-intensive care, and lack of standardized protocols (3-6). This review evaluates clinical evidence from 2014 to 2024 to clarify the current role of MLT in reconstructive surgery, emphasizing indications, outcomes, and practical recommendations for safe implementation.

MATERIALS AND METHODS

To evaluate the clinical impact of medicinal leech therapy (MLT) in modern reconstructive surgery, this study employed a two-part approach.

Retrospective Study. The study included 35 patients who underwent MLT for venous congestion following digital replantation at our center. Informed consent and psychological counseling regarding the use of leeches were obtained prior to treatment. All patients sustained traumatic digital amputations and underwent microsurgical replantation. Data extracted from electronic records included demographics (age, sex), comorbidities (e.g., diabetes, smoking status), injury mechanism, surgical details, timing and characteristics of venous congestion, and MLT specifics (timing, number and frequency of leeches, duration). Outcomes assessed were tissue salvage (defined as survival of the digit without reoperation or amputation), complications (infection, anemia, allergic reactions), and need for further interventions. MLT followed a standardized protocol: clinical diagnosis of congestion (aided by Doppler or oximetry), area cleansing with sterile saline, application of *Hirudo medicinalis* for 20-45 minutes, followed by post-detachment care with heparin-soaked gauze. Leeches were reapplied every 2-4 hours depending on severity, averaging 3 per day, until congestion resolved.

Literature Review. A structured narrative review was conducted following PRISMA guidelines, targeting studies published between January 2014 and March 2024. We searched PubMed, Scopus, and the Cochrane Library using MeSH terms and keywords including “leech therapy”, “plastic surgery”, “reconstructive surgery”, “digital replantation”, “venous congestion”, and “*Aeromonas hydrophila*”. Reference lists were screened manually for additional relevant articles.

Inclusion criteria were: adult human subjects receiving MLT for venous congestion in reconstructive or plastic surgery; clinical outcomes reported (e.g., tissue salvage, complications, transfusions); peer-reviewed English publications; all study types (case reports, series, observational studies). Exclusion criteria included pediatric cases, non-clinical reports, editorials, and non-English articles without accessible

translations. Duplicates and overlapping datasets were excluded.

A structured data extraction framework was used to capture: indications, timing of therapy, duration, frequency and number of leeches, antibiotic use (typically ciprofloxacin or TMP-SMX), anticoagulation, supportive care (e.g., transfusion), and outcome measures. Complications, particularly *Aeromonas hydrophila* infections, were a key focus (7-9). Other issues such as anemia, leech migration, allergic reactions, and psychological intolerance were also noted.

Due to heterogeneity in study design, protocols, and outcome measures, no meta-analysis was performed. Instead, findings were synthesized descriptively, allowing thematic analysis of trends, variations, and practical approaches. Institutional differences in technique-site preparation, leech placement, containment, and post-carewere documented to highlight real-world variability. This methodology reflects clinical reality and aims to guide evidence-informed decision-making in complex reconstructive scenarios. By consolidating a decade of experience, we offer practical insights into the use of MLT in contemporary microsurgery.

RESULTS

Retrospective study. Among the 35 patients, 10 cases (29%) involved amputations at the first phalanx (F1) level. In five of these, both arterial and venous anastomoses were performed; in the other five, only arterial repair was feasible. Venous congestion occurred early in two cases without venous repair and on postoperative day 3 in three cases due to venous thrombosis. Second phalanx (F2) amputations were recorded in 19 patients (54%). Arterial repair was achieved in all cases, but venous anastomosis was feasible in only six. In the remaining cases, venous outflow was compromised due to lack of suitable vessels.

Interrupted sutures were used sparingly to reduce trauma during skin closure. The remaining six cases (17%) involved distal phalanx (F3) amputations, where both arterial and venous repair were technically unfeasible due to small vessel caliber and extensive trauma. Replantation was limited to bony fixation and skin closure.

In all cases, a pulp incision with topical heparin was used to enhance passive venous drainage. Patients received 2-4 leeches daily for 4-7 days, with an average of three per day. Hemoglobin dropped below 9 g/dL in four F1-level cases, but no transfusions were needed. No patients experienced psychological intolerance to leech therapy. Overall, 31 patients (88.6%) achieved complete tissue salvage without necrosis or debridement. The four failures (11.4%) were due to arterial insufficiency or extensive soft tissue damage (e.g., degloving injuries).

In this cohort, the predominant trauma mechanism was clean-cut injury (12 cases), generally associated with sharp objects and favorable outcomes due to limited soft tissue damage. Crush injuries were identified in 10 patients, frequently resulting in significant vascular and soft tissue compromise. Avulsion (4 cases) and degloving injuries (5 cases) presented complex reconstructive challenges due to extensive tissue disruption and impaired venous outflow. Additionally, 4 cases involved saw or machinery-related trauma, typically combining sharp and blunt force components. The

nature of the traumatic insult significantly influenced surgical management and the indication for adjunctive therapies such as medicinal leech application.

Fig. 1. MLT preparation and application

The analysis was conducted to identify factors associated with the success or failure of medicinal leech therapy (MLT) in our cohort (tab. I).

TABLE I.
Analysis of factors affecting leech therapy success

Factor	Odds Ratio (OR)	95% C.I.	p-Value	Significance
Age (per year)	0.98	(0.95 - 1.01)	0.22	No
Diabetes mellitus (yes/no)	0.45	(0.12 - 1.67)	0.24	No
Peripheral vascular disease (yes/no)	0.32	(0.08 - 1.21)	0.09	No (trend)
Smoking history (yes/no)	0.56	(0.19 - 1.63)	0.28	No
Timing of leech initiation (/day delay)	0.78	(0.65 - 0.94)	0.008	Yes

Among all variables assessed, the timing of MLT initiation was the most significant predictor of tissue salvage. Patients who began therapy within 24 hours of venous congestion onset had significantly better outcomes than those with delayed initiation. Each additional day of delay reduced the odds of success (OR 0.78; 95% CI: 0.65-0.94; p = 0.008). This emphasizes the importance of early intervention, as delays may permit irreversible endothelial damage and thrombosis-pathologies less responsive to MLT (11-12). Other patient-specific factors-age, diabetes mellitus, peripheral vascular disease (PVD), and smoking status-were not statistically significant predictors of outcome. However, trends indicated poorer results among patients with PVD and active smokers (success rate 70% *vs.* 89% in non-smokers; p = 0.28), which aligns with known adverse effects of smoking and vascular disease on microcirculation and healing.

Treatment intensity parameters, such as

number of leeches per day and therapy duration, showed no clear association with outcome. These findings suggest that, once initiated appropriately, prolonging treatment or increasing leech quantity does not enhance efficacy. Rather, timely initiation remains the most critical determinant of success, provided therapy is continued until congestion is resolved. OR < 1 indicates a factor protective against failure (i.e., associated with higher success). For timing, OR 0.78 per day means each day's delay significantly lowered odds of success ($p < 0.01$). No other factor reached statistical significance in this sample, though PVD showed a non-significant trend toward worse outcomes.

Timely initiation of medicinal leech therapy (MLT) remains the key determinant of success in managing venous congestion following reconstructive surgery. In our cohort of 35 patients, early application was associated with favorable outcomes across all subgroups, including those with diabetes, peripheral vascular disease (PVD), and smoking history. Although no statistically significant differences were found between these subgroups, the sample size limits definitive conclusions. Complications were consistent with known risks of MLT and were generally manageable. Two patients (6%) developed *Aeromonas* infections, treated effectively with intravenous antibiotics and local care, though one case resulted in partial flap necrosis. These findings highlight the importance of routine prophylactic antibiotics and close monitoring. Anemia occurred in 5 patients (14%) with hemoglobin drops >2 g/dL, managed conservatively without transfusion. Mechanical issues such as leech migration or detachment were rare and easily corrected. Mild psychological discomfort was reported but did not affect compliance; tolerance improved with simple measures like leech concealment or light sedation. No allergic reactions or early terminations were observed. Overall, MLT was safe, effective, and well-tolerated when initiated promptly and managed within a structured protocol, supporting its continued role in microsurgical salvage.

Literature review. The initial literature search across PubMed, Scopus, and Google Scholar (January 2014-March 2024) identified 134 records. After removing 26 duplicates, 108 unique articles underwent title and abstract screening. Of these, 50 were excluded for not meeting inclusion criteria. Common reasons for exclusion included irrelevance to reconstructive surgery, lack of clinical outcomes, non-human or experimental data, and the application of leech therapy in unrelated medical fields. The study selection process is summarized in second figure.

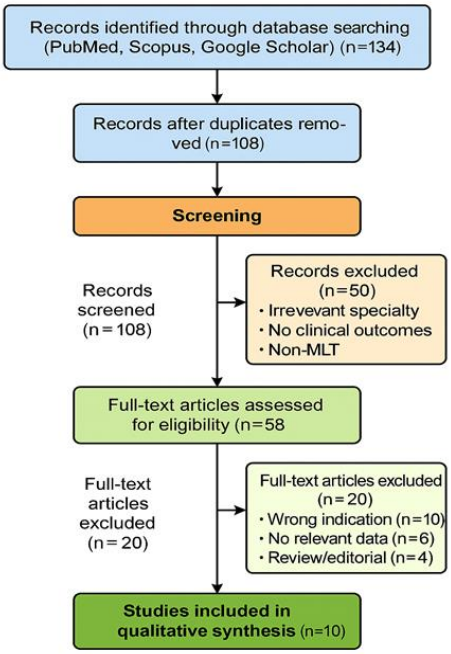

Fig. 2. PRISMA flow chart

Following initial screening, 58 full-text articles were reviewed for eligibility. Of these, 20 were excluded: 10 for incorrect clinical indication, 6 for lacking relevant outcome data, and 4 for being editorials or reviews without original data. Ultimately, 10 studies met all predefined inclusion criteria and were included in the qualitative synthesis. These articles were selected independently by the authors for their focus on the clinical use of medicinal leech therapy in managing venous congestion and for providing detailed information on treatment protocols, outcomes, and complications (tab. II).

TABLE II.

Results of the selected studies

Authors	Clinical indication	Surgical technique	Timing of leech application	Time of therapy	Number of leeches	Application time	Number of sessions
1. Horoz L, Çakmak MF (2023)	Venous congestion after digital replantation or revascularization	Digital arterial-only replantation	Immediately postoperatively if no venous repair is possible or venous congestion is present	5 days, but can extend to 10-12 days for proximal amputations	leeches changed every 2 hours	15 minutes to 2 hours per leech	Applied at 2-6 hour intervals initially, adjusted based on congestion and bleeding (mainte-(maintenance interval 4-8 h); varies by case
2. Pickrel *et al.*, (2020)	Venous congestion post digital replantation/ revascularization	Artery-only or venous anastomosis finger/digit replantation	Prophylactic (immediate) or at first sign of congestion (preferably <24-48 hrs)	5-7 days; weaning after 5 days if stable	Not standardized; 2-hour intervals mentioned; ~2-3/day	30-60 minutes, followed by passive bleeding for up to 6 hours per site	Every 2-3 hours as needed, depending on signs of congestion
3.Z-Hye	Venous	Microsurgical	At clinical		Applied		Every

Authors	Clinical indication	Surgical technique	Timing of leech application	Time of therapy	Number of leeches	Application time	Number of sessions
Lee *et al.,* (2019)	congestion after finger/digit replantation or revascularization	replantation or revascularization of digits	signs of congestion (e.g. dark blood, capillary refill >2s, edema)	Mean of 7 days (range 1-20)	every 1-4 hours; ~2-5 per day (not precisely quantified per patient)	~30-90 minutes per session (implied standard; not directly stated	1-4 hours
4. Arami *et al.,* (2018)	Venous congestion in replanted or revascularized fingers (proximal/middle phalanx level)	Digit replantation and revascularization	Diagnosed late: 24/25 after 48 hours, 1 case at 32 hours after surgery	Mean 2.3 days (range 1-5 days)	Mean 2.88 (range 1-8)	standard detachment assumed (~30-45)	1-3 times per day
5. Cornejo *et al.,* (2017)	Venous congestion after flap surgery or digital replantation	Pedicled and free flaps, digit/appendage replantation	Postoperative, at first signs of venous congestion	Average 4.6 days (range 1-11)	Mean 24.8 per patient (reported only in 14 cases; range 2-77)	20-45 minutes until detachment Followed by passive bleeding for up to 4-6 hours at the site	Not consistently reported; estimated every few hours depending on severity
6. Herlin C *et al.,* (2016)	Venous congestion after finger replantations and flap salvage	Finger replantations and flap salvage	Early application in postoperative hours when signs of venous congestion were noted	6.3 days (range 4-10 days)	Every 2-4 hours initially, then adjusted individually based on congestion	15 minute to 2 hour per leech	Continuous until decongestion stopped progressively between day 5-7
7. Marcia Spear *et al.,* (2016)	Venous congestion in plastic surger - primarily for replants, digit transplants	digital replantation	As soon as venous congestion diagnosed	3-7 days or until angiogenesis reestablished	1-2 per site per session	20-45 minutes per leech session	Every few hours, based on clinical assessment
8. Authors	Clinical indication	Surgical technique	Timing of leech application	Time of therapy	Number of leeches	Application time	Number of sessions
	nasal tips)						
9.Whitaker *et al.,* (2012)	Venous congestion in reconstructive and microsurgery (replants, flaps, avulsions, etc.)	Variety: replantation (ears, lips, digits, nose, penis), degloving injuries,	When clinical signs of venous congestion appeared	Variable - from a few hours (20 hours) up to 22 days (mean: ~5-7 days)	Ranged from 1/day to 1/hour; in some cases, up to 100 leeches total	Commonly 20-60 min per leech, detachment usually spontaneous	2-8/day depending on severity; most common: every 2-4 hours
10. PA Green *et al.,* (2010)	Venous congestion after microsurgical tissue transfer, digital replantation, free flaps	digital replantation (distal to FDS insertion)	Early application upon signs of venous congestion or prophylactically in venous repair impossibility	~4.2 days average; 7-10 days in case examples	3-6 per application new applie when bleeding stops	Until detachment (~30-90 minutes); 2.45 mL active, 2.5 mL passive blood loss per	Every 2-4 hours initially, based on clinical status

Medicinal leech therapy (MLT) continues to play a valuable role as an adjunctive measure in reconstructive microsurgery, particularly in cases where venous outflow cannot be established through conventional means, such as digital replantation (10-12,13-16). Its ability to provide temporary venous drainage through biologically active decompression makes it a cost-effective and practical alternative when technical limitations or vessel unavailability preclude venous anastomosis (17). In our series, MLT proved to be both effective and well-tolerated across a wide range of patients, including those with comorbidities such as diabetes, peripheral vascular disease, and active smoking history (19-21). Although no statistically significant differences in outcome were noted across these subgroups, observed trends support the established negative influence of vascular comorbidities on healing potential (22).

Complications were consistent with the known risk profile of MLT. Infections occurred in 6% of cases, both due to *Aeromonas* species, and were managed successfully with intravenous antibiotics and wound care (23). These findings reaffirm the necessity of routine prophylactic antibiotic coverage and close clinical monitoring. Anemia was observed in 14% of patients, but all cases were managed conservatively without transfusion. Mechanical issues such as leech detachment or migration were infrequent and easily corrected. Patient tolerance was high, with no therapy discontinued due to psychological distress or adverse reactions (24). A focused comparison between early (< 24 hours) and delayed (> 48 hours) initiation of medicinal leech therapy (MLT) revealed clinically significant differences in therapeutic outcomes and intensity of care. Early MLT was associated with a higher tissue salvage rate (78.14%) compared to 71.00% in the delayed group, reinforcing the importance of timely decompression prior to the onset of irreversible endothelial injury and thrombosis. Moreover, early initiation resulted in longer average treatment duration

(5.29 *vs.* 3.67 days) and more intensive therapy, including a higher number of leeches per day (3.86 *vs.* 3.00) and sessions per day (3.57 *vs.* 2.67). This pattern indicates increased clinical engagement during the critical early postoperative period, allowing more effective venous drainage. The early MLT group also demonstrated a broader therapeutic range, with durations spanning 4-7 days and leech applications ranging from 2 to 6 per day, compared to 2-6 days and 2 to 5 leeches per day in the delayed cohort (25-27). Although the average transfusion rate was slightly higher in the early group (49.29% *vs.* 41.67%), this was likely reflective of more aggressive decompression and prolonged bleeding rather than increased risk, as no rise in major complications was observed (28). These findings suggest that while treatment intensity can be adjusted, delayed MLT initiation compromises outcomes, likely due to progressive micro-vascular damage that becomes non-reversible. The survival benefit with early therapy supports the recommendation that MLT be initiated within 24 hours of congestion onset whenever possible. To ensure both efficacy and safety, structured institutional protocols are essential to guide standardized, timely MLT across surgical teams.

DISCUSSION

Venous congestion remains a critical complication following digital replantation or revascularization, particularly in distal digit injuries where venous outflow is compromised due to avulsed, thrombosed, or non-reconstructible veins. In such cases, medicinal leech therapy (MLT) offers a biologically active adjunct to promote passive drainage until intrinsic venous outflow or neovascularization is established. The study evaluated key clinical variables of MLT-including initiation timing, duration, application frequency, and complications-in a cohort of 35 patients. The observed tissue salvage rate of 88.6% compares favorably with literature-reported rates (66-85%), likely reflecting early therapy initiation (average 1.5 days post-op; most within 24 hours) and adherence to a standardized institutional protocol. Early initiation was statistically associated with improved outcomes ($p = 0.008$). MLT was administered for an average of 5 days, with 2-4 leeches applied daily at 2-4-hour intervals. Feeding durations ranged from 20 to 45 minutes. These parameters align with current best practices. Complication rates were low: *Aeromonas hydrophila* infections occurred in 6% of cases, and 14% developed mild anemia, though no transfusions were required. Minor issues such as leech migration or patient discomfort were infrequent and easily managed. The favorable outcomes observed may be attributed to care according to protocols and consistent use of prophylactic antibiotics-ciprofloxacin-combined with rigorous clinical monitoring. This contrasts with the variability in technique, antibiotic use, and therapy duration noted across many published studies. Salvage rates above 75% are commonly reported when therapy is initiated within 24-48 hours and maintained for at least 4-5 days. Delayed initiation, particularly beyond 48 hours, correlates with decreased viability, despite intensified treatment. Findings from Arami *et al.* and Lee *et al.* support this time-sensitive therapeutic window, with the latter demonstrating improved digital survival when MLT exceeded 4.5 days (29-31). Treatment regimens in published reports generally involve 2-5 leeches per day, applied every 2-4 hours.

Leeches are allowed to feed until detachment, followed by prolonged passive bleeding, which facilitates decompression and enhances perfusion. Adjunctive measures-limb elevation, thermal vasodilation, and heparinized dressings-are frequently used to support MLT efficacy (32). Reported infection rates range from 4% to 20%, most commonly involving *Aeromonas hydrophila*, reinforcing the necessity of antibiotic prophylaxis (33). Anemia, often proportional to therapy duration and leech count, results in transfusion rates up to 60% in some series. In our cohort, careful monitoring and supportive care prevented the need for transfusion (34). Based on this analysis, the following recommendations are proposed for MLT in digital replantation: initiate therapy within 24 hours of venous congestion, apply 2-5 leeches per day, adjusting for severity and surface area, 2-4-hours intervals; allow leeches to feed until detachment, maintain therapy for at least 4 days; taper as clinical improvement is observed, use prophylactic antibiotics (e.g., ciprofloxacin) throughout the treatment period, employ adjuncts such as analgesia, limb elevation, heparin-soaked gauze, and daily hemoglobin monitoring (35).

MLT remains an effective, time-sensitive, and manageable adjunct in the management of venous congestion after digital replantation. When initiated early and guided by protocol, MLT significantly improves tissue salvage in settings where conventional venous repair is not feasible.

CONCLUSIONS

Medicinal leech therapy (MLT) remains a biologically active, evidence-supported, and time-tested adjunct in the management of venous congestion following digital replantation and revascularization. Despite advances in microsurgical techniques, venous congestion continues to pose a significant threat to digit viability, especially in distal replantation where venous outflow cannot be surgically restored. In these high-risk cases, MLT offers a minimally invasive solution that facilitates temporary venous drainage, promotes tissue oxygenation, and allows time for neovascularization.

Although leech therapy remains underutilized in some centers, current evidence from the past decade supports its continued integration into microsurgical practice, particularly when initiated promptly and guided by structured protocols.

COMMUNICATION BETWEEN MEDICAL LABORATORY AND CLINICAL DEPARTMENTS - INSIGHTS FROM A SURVEY AMONG ROMANIAN HEALTHCARE PROFESSIONALS (Abstract): Effective patient management can be achieved through extensive collaboration and synchronized action between specialists in paraclinical investigations and attending physicians. However, in practice, proper communication is often difficult to establish and maintain. This study **aims** to assess the communication between laboratory staff and clinicians among Romanian healthcare professionals. **Materials and methods:** an online survey consisting of questions with pre-defined answers was conducted to gain insights into the experiences and opinions of Romanian healthcare professionals regarding communication between clinical departments and the medical laboratory. Results: the survey was completed by 176 respondents, covering all categories of healthcare personnel from both medical laboratories and clinical departments. Overall, laboratory staff reported that they most often communicate promptly about test availability, while respondents from clinical departments felt they were informed about these aspects less frequently. The results also highlight a potential need among medical laboratory staff to be more involved in case discussions and to be more respected as healthcare professionals. **Conclusions:** this study provides relevant insights that can inform future research and initiatives aimed at improving collaboration between clinical and paraclinical departments, with the potential to significantly enhance patient management. **Keywords:** PATIENT MANAGEMENT, MEDICAL LABORATORY, COMMUNICATION.

INTRODUCTION

Paraclinical investigations are an essential part of the diagnosis and treatment process nowadays, with the medical laboratory playing a significant role in patient management (1). Inaccurate or delayed results, as well as suboptimal laboratory infrastructure, might substantially influence the outcomes. However, besides the technical aspects of the laboratory work, there are a few more factors contributing to effective and optimal results. The lack of necessary clinical data submitted with the test order, as well as the failure to promptly contact the clinical team when necessary could result into missing important and vital information regarding the patient (2). The tendency of clinicians to require many unnecessary tests

is common and leads to increased healthcare costs, as well as additional pain and discomfort (3). Even more, the increasing number of unjustified required tests leads to more false positive results, which will require more testing (4). Reasons include the misunderstanding of benefit/harm ratio, the lack of knowledge regarding the costs of tests, as well as the fear of misdiagnosing (5). An improved interaction between clinical and laboratory teams might address these issues. Therefore, a better communication between laboratory and clinical staff might contribute to an increased general satisfaction, reduced healthcare costs and improved patient outcome. The purpose of this study is to highlight new insights on the communication between medical laboratories and clinical departments in Romanian healthcare institutions.

MATERIALS AND METHODS

An online questionnaire (Google Forms) with pre-defined answer options was used as the data collection instrument. The form was distributed among healthcare professionals and was open to participation regardless of their role or professional title. The questionnaire was structured into separate sections tailored for two distinct groups: healthcare professionals working in clinical laboratories and those working in clinical departments. The questions in both sections were designed to address related themes, enabling the comparison of perspectives between laboratory staff and clinicians on shared topics. Survey participation was entirely voluntary. The form was publicly accessible, and completion of the questionnaire was considered as implied consent. Introductory information outlining the study's purpose was provided at the beginning of the form. Only respondents who agreed to participate in the study could proceed to the sections with the questions.

Data collection relied on a general-purpose instrument rather than a validated questionnaire, with the goal of exploring broad perspectives and identifying emerging topics of interest, rather than producing generalizable or statistically rigorous findings. Responses were compiled and processed using the built-in features of Google Forms, along with *Microsoft Excel*. Descriptive analysis was performed, with results expressed as relative frequencies and illustrated through tables and graphical representations.

RESULTS

The survey was filled in by 176 respondents, 53.4% who work in clinical departments, while 46.6% work in clinical laboratories. From the respondents working in clinical laboratories, 53.8% were physicians, 39% were clinical biologist/ biochemist/ chemist, and 6.1% were nurses, as detailed in figure 1. 18.3% of the respondents who work in clinical laboratories reported being head of laboratory, and among this group of respondents, 47.6% work in the public healthcare system, 41.5% in private laboratories and 11% in both.

Among the respondents who work in clinical departments, 14.9% do not work in a healthcare facility that has a clinical laboratory, therefore only 80 out of 94 respondents who work in clinical departments were able to answer the questions about the communication with the clinical laboratory. Of them, 95% were physicians and the others were nurses, and 3.8% of the respondents in this group were head of department. Among respondents who work in clinical departments, 81.3% work in public healthcare facilities, 7.5% in private healthcare facilities and 11.3% in both (fig. 1).

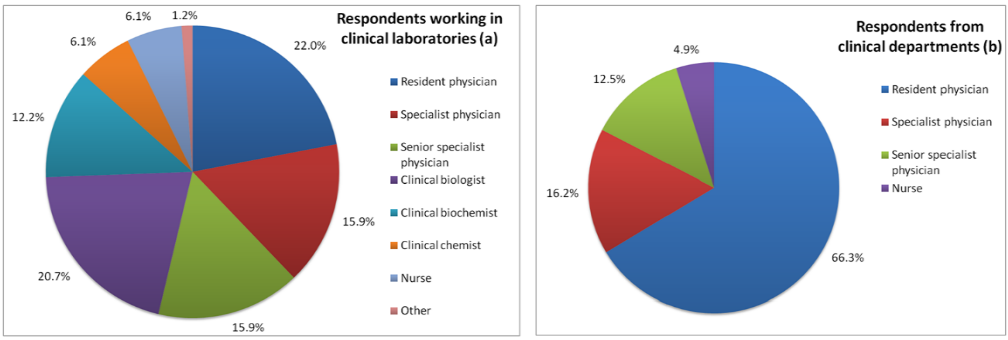

Fig. 1. Professionals from laboratories (a), and clinical (b) departments among respondents

Table I presents, as relative frequencies, the responses to the questions regarding communication between clinical laboratory staff and clinical department personnel, highlighting both perspectives. Figure 2 illustrates the level of satisfaction reported by laboratory staff regarding their collaboration with clinicians and vice-versa, based on several aspects of interdepartmental collaboration and workflow. Respondents rated their satisfaction on a scale ranging from 'Not at all satisfied' to 'Very satisfied'.

TABLE I.

Medical laboratory and clinical department communication – perspectives from both sides

Respondents	Medical laboratory personnel	Clinical department personnel
Frequency of communication between medical laboratory and clinical department		
Never	9.8%	10%
Several times a day	26.8%	12.5%
Daily	20.7%	18.8%
A few times a week	23.2%	28.7%
A few times a month	11%	18.8%
A few times a year	6.1%	11.3%
Other	2.4%	0%
Who initiates direct laboratory-clinical communication?		
Us	31.7%	50%
The others	12.2%	3.7%
Both	51.2%	35%
Not applicable	4.9%	11.3%
What are the topics of discussion?		
Interpretation of laboratory test results for specific patients and cases	89%	77.5%
Available methods, equipment and tests	31.7%	31.3%
Intention to implement new laboratory tests	30.5%	8.8%
Lack of reagents	26.8%	30%

Respondents	Medical laboratory personnel	Clinical department personnel
When new tests are available in the laboratory, are the specialists from clinical departments promptly and in detail informed about the possibility of requesting them?		
Always	57.3%	13.8%
Most of the time	23.2%	27.5%
Sometimes yes, sometimes no	9.8%	18.8%
Most of the time no	1.2%	15%
Never	0%	8.8%
Not applicable	8.5%	16.2%
Do you consider it necessary to involve the medical laboratory staff in discussions with the clinic specialists about the results obtained and their interpretation?		
Always	51.2%	12.5%
Most of the time	32.9%	20%
Sometimes yes, sometimes no	13.4%	55%
Most of the time no	2.4%	10%
Never	0%	2.5%
What do you consider to be most important to communicate between the medical laboratory and the clinical departments?		
Case discussions and interpretation of results in both clinical and technical contexts	26.8%	27.5%
Discussions about tests that are available or unavailable over time	2.4%	10%
Dynamic variation of waiting times, related to the availability and management of medical laboratory resources	6.1%	17.5%
All these are equally important	64.6%	45%
When laboratory tests cannot be performed due to problems related to reagent management and procurement or technical issues, are clinic specialists promptly informed of this?		
Always	48.8%	13.7%
Most of the time	17.1%	17.5%
Sometimes yes, sometimes no	8.5%	20%
Most of the time no	6.1%	25%
Never	2.4%	12.5%
Not applicable	17.1%	11.3%
Is there a procedure that refers to communication between laboratory and clinical department in your institution?		
Yes, but I don't know its contents.	11%	6.3%
Yes, but its content is not followed	6.1%	1.2%
Yes, and its content is followed most of the time	43.9%	10%
There is no procedure	12.2%	17.5%
I do not know if the procedure exists	25.6%	65%
Other	1.2%	0%

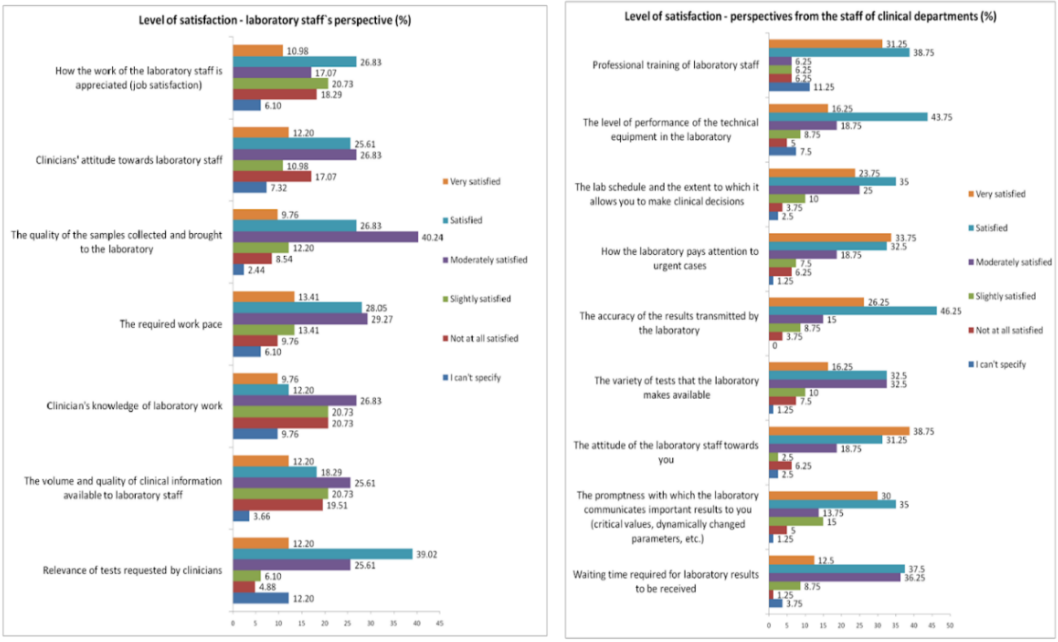

Fig. 2. Satisfaction level reported respondents concerning the laboratory - clinical department collaboration

From all the above, the respondents who work in clinical laboratories chose as the main aspect they appreciate in their collaboration with clinicians both the relevance of tests requested by clinicians (22%) and the volume and quality of clinical information available to laboratory staff (23%), followed by how the work of the laboratory staff is appreciated - job satisfaction (20.7%), the quality of the samples collected and brought to the laboratory (13.4%), clinicians' attitude towards laboratory staff (8.5%), clinician's knowledge of laboratory work (7.3%), and the required work pace (2.4%).

From all the above, the respondents who work in clinical departments chose as the main aspect they appreciate in their collaboration with laboratory personnel the promptness with which the laboratory communicates important results to them - e.g. critical values, dynamically changed parameters etc. (33.8%), followed by the attitude of the laboratory staff towards them (16.3%), the variety of tests that the laboratory makes available (13.8%), waiting time required for laboratory results to be received (11%) and the accuracy of the results transmitted by the laboratory (11%), how the laboratory pays attention to urgent cases (6.3%), the lab schedule and the extent to which it allows them to make clinical decisions (5%), the professional training of laboratory staff (5%) and the level of performance of the technical equipment in the laboratory (1.2%).

Table II presents the perspectives of both the medical laboratory personnel and clinical department staff on the main challenges in their communication.

TABLE II.
Challenges for the communication between medical laboratories and clinical departments

Opinions on the main problem in communication			
Laboratory staff		**Clinicians**	
Lack of formal communication means	35.4%	Lack of formal communication means	60%
Lack of openness on the part of clinicians to communicate	9.8%	Lack of openness on the part of laboratory staff to communicate	10%
Clinicians' attitude towards specialists working in the laboratory	48.8%	The attitude of laboratory staff towards specialists working in the clinical departments	7.5%
Others	6%	Others	22.5%

DISCUSSION

Given the critical role of laboratory test results in clinical decision-making, medical laboratories are a key component of collaborative healthcare, where the patient is increasingly seen as an active participant alongside healthcare professionals (6). Considering the continuous increase in the complexity of technological advances in laboratory medicine, collaboration between the medical laboratory and clinicians has been highlighted since the late 20th century as a critical issue requiring innovation (7). Furthermore, the interpretation of laboratory test results goes beyond simply classifying values as within or outside the biological reference range or considering only the analytical performance (8).

While the importance of communicating critical and alert values of laboratory tests has been widely recognized (9-19) and usually there are procedures implemented for this purpose (11), the need to integrate laboratory specialists into case-related decisions has gained more and more interest, for example, in the field of medical microbiology (12), a subspecialty of laboratory medicine (13). Collaboration with laboratories covers all sectors of healthcare, from primary care to precision medicine (14-16)

Effective laboratory-clinical department communication must be bidirectional, should involve all categories of healthcare personnel, can use all means of communication and should be facilitated by the management (17). Laboratory-clinician communication improvement can be achieved through standardized, clear reporting (18). The collaboration between clinical and paraclinical departments is influenced by organizational and managerial factors within institutions and departments, as well as by socioeconomic, cultural, and educational factors, alongside the individual knowledge and skills of each healthcare professional (19,20). The present study identified both similarities and differences in the experiences and perceptions regarding collaboration between clinical laboratories and clinical departments in Romania. While some aspects, such as the frequency of communication, were perceived relatively similarly by both groups of respondents, other perceptions varied significantly. For example, in relation to the implementation of new tests or testing methods, 80.5% of respondents working in

medical laboratories stated that clinicians are always or almost always informed in a timely manner about the availability of these investigations, whereas only 41.3% of clinicians shared this view. This discrepancy was also reflected in the responses to the question concerning the topics of communication between laboratory and clinical staff. Specifically, the intention to implement new tests was mentioned as a topic of communication by 30.5% of laboratory staff, but by only 8.8% of clinical department respondents.

Respondents working in medical laboratories expressed a strong interest in being involved in discussions regarding test results and their interpretation, with 84.1% believing that such discussions should occur always or almost always. Clinicians, however, were more reserved about the necessity of this type of communication: 55% considered it necessary only sometimes, and just 32.5% opted for always or most of the time.

Another notable difference between the two groups emerged in relation to communicating the inability to perform certain tests due to issues such as reagent supply or technical problems. While 65.9% of laboratory staff stated that this is always or most of the time communicated to clinicians, only 31.2% of clinical department respondents reported the same.

Regarding the regulation of communication between the laboratory and clinicians within institutions, 61% of respondents working in medical laboratories reported the existence of a formal procedure, with 43.9% stating that its content is routinely followed. In contrast, 65% of respondents from clinical departments were unaware of whether such a procedure exists in their institution. This is particularly notable given that 60% of respondents from clinical departments also identified the lack of formal communication channels as a main issue in laboratory-clinician collaboration. Meanwhile, among respondents working in medical laboratories, the most frequently reported problem was the clinicians' attitude towards laboratory specialists (48.8%).

Overall, most respondents from clinical departments reported being satisfied or very satisfied with the various aspects of their collaboration with the medical laboratory, as evaluated in this survey. This can vary from one healthcare system to another, for example Fondoh *et al*. reported a high level of dissatisfaction among clinicians about their collaboration with medical laboratories (21). A larger study conducted in the United States concluded that the clinicians from emergency departments are generally dissatisfied regarding laboratory services that was reduced after corrective actions (22) A survey conducted at the beginning of 2000s in Finland aimed to identify topics of dissatisfaction among clinicians about laboratory investigations (23). After corrective measures were implemented, no improvement in the level of dissatisfaction was identified, suggesting that achieving optimal collaboration between clinical and paraclinical departments is a major challenge.

The current study offers valuable insights into various aspects of communication between laboratory staff and clinicians, highlighting potential trends among healthcare professionals and guiding future research aimed at improving collaboration between clinical and paraclinical departments. However, the results are limited by

the subjectivity of the responses, the modest number of participants, and the use of a general data collection tool rather than a validated questionnaire. Nevertheless, this exploratory study design was appropriate for rapidly identifying key issues that warrant further investigation.

CONCLUSIONS

There is a clear communication gap between laboratory and clinical staff, suggesting that targeted strategies to improve timely and effective information exchange are essential for optimal patient care.

A need for greater recognition and inclusion of medical laboratory professionals in interdisciplinary case discussions was identified, promoting mutual respect and collaborative decision-making.

Discrepancies between clinical and laboratory staff perceptions of communication frequency highlight the importance of establishing standardized communication protocols.

Structured and regular interactions between paraclinical and clinical departments could help align expectations and foster trust, thereby improving healthcare delivery.

The insights gained call for further investigation into the root causes of communication challenges and the development of institutional policies that promote integrated teamwork across all levels of healthcare provision.

ACKNOWLEDGEMENTS

The research group was formed with the support of the Medical Research education project (https: //ssmb.ro/departamente/#scome) of the Medical Students' Society of Bucharest (SSMB).

CONFLICT OF INTERESTS AND FUNDING

The authors have no conflict of interests to declare and the study received no funding.

ANALYSIS OF POSTOPERATIVE PAIN SCORES AND CLINICAL CHARACTERISTICS IN PATIENTS ASSOCIATING OBSTETRICAL AND GYNECOLOGICAL INTERVENTIONS IN NORTH-EASTERN ROMANIA

G. V. Tănase[1], Adina Elena Tănase[1*], Manuela Ciocoiu[1], C. G. Ilea[1]

ANALYSIS OF POSTOPERATIVE PAIN SCORES AND CLINICAL CHARACTERISTICS IN PATIENTS ASSOCIATING OBSTETRICAL AND GYNECOLOGICAL INTERVENTIONS IN NORTH-EASTERN ROMANIA (Abstract): Pain is a vital function of the nervous system, providing the body with a warning of potential physical or psychological injury. Nociceptors are specialized sensory structures involved in the detection of potentially harmful stimuli. They transform noxious stimuli - whether mechanical, thermal or chemical - into electrical signals that are transmitted to the central nervous system via primary afferent fibers of the Aδ and C types. **Materials and methods**: We describe the analysis of a representative cohort of 111 patients, which we analyzed for our study characteristics: age, environment of origin, type of intervention performed, length of hospitalization, pain score, recovery period in hospital. We obtained a study group formed by gynecological and pregnant patients who presented for surgical interventions at the "Cuza-Vodă" Obstetrics and Gynecology Clinical Hospital in Iași between 01.12.2024 and 01.12.2025, that were included in the analysis. **Results:** A wide number of clinical data were analyzed starting with demographic characteristics, type of surgery, number of days of hospitalization, neonatology results. The main statistically significant correlation was a reduced Apgar score at gestational age less than 38 weeks**.** A complex interplay between the various biological responses of the immune system, the autonomic nervous system, vascular regulation, and the central and peripheral nervous systems in response to tissue injury, pathogens, and irritants comprises the sensation of pain by the body. Pain can then play a vital protective role for an organism, as is the case with acute inflammation that results in the perception of pain, leading to avoidance of noxious stimuli and encouraging healing of damaged tissue. **Conclusions:** Adequate management of post-cesarean pain remains a challenge in the hospital. Better interprofessional collaboration, self-administered analgesia, scheduled medical prescriptions and increased availability of analgesic medications may contribute to improving postoperative pain management, with better pain scores. **Keywords:** ANESTHESIA, PAIN, SURGERY, PATIENTS, HOSPITALISATION DAYS.

INTRODUCTION

Postoperative pain can negatively affect both the general physical and psychological condition of a patient, also suppressing their motivation to recover and mobilize as quickly as possible postoperatively, as pain is associated with a reduced ability to accept the doctor's advice, increased psychological stress and a general repression of resuming daily activities.

In contrast, effective pain management promotes the motivation for early patient

mobilization, allowing for improved recovery, facilitating necessary movements and deep breathing, and reducing the negative physiological and psychological impact of pain (1).

Key factors in addressing this problem include comprehensive patient education about pain management options, shared decision-making with healthcare providers, and implementation of specialized and individualized patient-based services and therapeutic regimens for acute postoperative pain (2). Due to the global increase in surgical interventions in the gynecological sphere, along with the global increase in the incidence of cesarean sections (in some cities in Italy or Brazil the incidence reaches 90%), there is currently a greater emphasis on increasing the quality of the surgical act as a whole, including postoperative care and pain management in the anesthesia and intensive care unit.

Pain is a vital function of the nervous system, providing the body with a warning of potential physical or psychological injury. It is both a sensory and emotional experience, influenced by psychological factors such as past experiences, beliefs about pain, fear, or anxiety (3). Nociceptors are specialized sensory structures involved in the detection of potentially harmful stimuli (4). They transform noxious stimuli - whether mechanical, thermal or chemical - into electrical signals that are transmitted to the central nervous system via primary afferent fibers of the Aδ and C types, whose free nerve endings are spread throughout the entire structure of the organism: skin, viscera, muscles, joints and meningeal structures (5).

Pain is, by its nature, a complex and multifactorial phenomenon, difficult not only to treat but also to fully understand. It involves interactions between sensory, affective, and cognitive components, leading to recognition, interpretation, and appropriate emotional response (6-11). From the perspective of the anesthesiologist and the intensive care specialist, understanding and managing pain is a major area of interest, as peri- and postoperative pain is a common reality in clinical practice, requiring effective and personalized therapeutic approaches (7). In addition, growing concerns about the excessive use of opioids in the treatment of acute and chronic pain have generated an urgent need to develop alternative and multimodal pain control strategies (8). In this context, anesthesiologists are increasingly exploring the combined use of pharmacological therapies, such as nonsteroidal anti-inflammatory drugs (NSAIDs), antidepressants, corticosteroids, alpha-2 receptor agonists, ketamine, local anesthetics, magnesium, gabapentinoids, and acetaminophen (9, 10).

MATERIALS AND METHODS

We describe the analysis of a representative cohort of 111 patients, which we analyzed for our study characteristics: age, environment of origin, type of intervention performed, length of hospitalization, pain score, recovery period in hospital. We searched for correlations between patient characteristics, surgery and the registered VAS score associated with the surgery, and recovery period. The motivation of this study was given by monitoring the general well-being of patients in the immediate postoperative period, with the interest of reducing the adverse effects of the types of anesthesia performed - locoregional or general, such as: pain, nausea, chills. Also, a low pain score is associated in specialized articles with better postoperative recovery, faster resumption of intestinal peristalsis, and a decrease in the number of days of hospitalization.

Study group. Gynecological and preg-

nant patients who presented for surgical interventions at the Cuza-Vodă Obstetrics and Gynecology Clinical Hospital in Iași, between 01.12.2024 and 01.12.2025, were included in the analysis.

Inclusion criteria were formed by: age above 18 years and associated obstetrical or gynecological surgical intervention.

Exclusion criteria were patients under 18 years of age; persons with suspected sepsis or associated severe medical pathologies.

General objectives were to evaluate the effectiveness of the treatment of postoperative pain noted as mild, moderate to severe pain in the group of patients studied, in order to differentiate between the importance of major obstetric or gynecological associated risk factors and the extent of the surgical intervention. The study was descriptive, prospective and retrospective, starting from the surgical intervention performed, analyzing clinically and paraclinically, the importance of the relationships between demographic characteristics, associated medical pathology, physiological and pathological medical history and the pain score represented on the VAS scale, respectively the correlations between demographic characteristics, surgical intervention and associated postoperative pain score.

Statistical analysis. Both descriptive and analytical methods were used in the statistical analysis. After collecting the data, in an accessible form to ensure their informational character, their processing was carried out.

The processing actions included the stage of ordering, systematization, centralization and reduction of the volume of information collected, through successive operations of grouping, sorting, coding and synthesizing. The data were expressed in a form that allows them to be classified into certain categories; a variable will not be recorded in more than one form; the data will be grouped by variable categories. The data were centralized in *Microsoft Excel* and *SPSS* databases and processed with the statistical functions to which they are suitable. In the presentation of the data, confidence intervals at the 95% significance threshold were used, and the χ^2 and t-Student tests were used to test the differences.

RESULTS

With the increase in the number of surgical interventions worldwide, but the decrease in the global birth rate, the medicalization of births has occurred and has become an increasingly common practice, therefore we present our patients characteristics and VAS scores according to the surgery they had performed.

Demographic characteristics

Age group distribution. The series of values for age has a normal distribution: variations in the range of 20-79 years; group mean 37.17 years ± 11.40; median 36 years; Kurtosis test result 1.644 and p>0.05 for the Kolmogorov-Smirnov test, which suggests that statistical significance tests can be applied for continuous variables. Based on these data, the age of 36 years (50th percentile) is chosen as the threshold for subsequent correlations, 50.5% of the patients were over 36 years old.

Distribution by area of origin. Out of the total of 111 study group patients, 77 patients were of urban origin, of which 54.5% were over 36 years old, while in the patients of rural origin the age was predominantly under 69 years old (58.8%) (p=0.137).

Clinical characteristics.

Surgical interventions

Out of the total study group (n=111), 52.3% of the analyzed patients underwent cesarean sections (n=54 CST), respectively 14.4% underwent interventions such as total hysterectomy with bilateral adnex-

ectomy (n=16HT+AB) and 9% underwent biopsy curettage (n=10).

Cesarean section surgery. Of the 58 patients with cesarean section, 79.3% were under 36 years of age, while 83% of patients with other types of surgery were over 36 years of age (p=0.001). The structure of the group of patients with cesarean section was predominantly urban (63.8% *vs.* 75.5%; p = 0.130).

Patient gestation. In patients with cesarean section, the series of gestation values varied in the range 1-7, with a mean value of 2.07±1.13 close to the median value of 2, but it does not seem to be normally distributed because the Kurtosis test values> 2 and the Kolmogorov-Smirnov test values < 0.05, which suggests that statistical significance tests cannot be applied for continuous variables. Of the total group of patients with cesarean section, 22.2% had over 3 gestations.

Among patients with gestation under 3 pregnancies (n=42), 83.3% were under 36 years of age, and 71.4% came from urban areas. Among the patients with more than 3 pregnancies (n=12), 75% were under 36 years of age (p=0.389), and 58.3% came from rural areas (p=0.05).

Parity of the analyzed patients. Parity varies in the range 1-4; group mean 1.72 ± 0.76; median 2; Kurtosis test result 1.249 and p>0.05 for the Kolmogorov-Smirnov test, which suggests that statistical significance tests can be applied for continuous variables.

In the case study, the Pearson test revealed that parity was not correlated with age (r= +0.079; p=0.570). In patients from rural areas, parity was higher than in those from urban areas (2.0 *vs.* 1.57; p=0.048)

Number of weeks of pregnancy at which delivery occurred by cesarean section. In patients with cesarean section, the series of values for the number of weeks of pregnancy varies in the range of 31-40; group average 37.94 weeks ± 1.56; median 38 weeks; Kurtosis test result 7.951 and p<0.05 in the Kolmogorov-Smirnov test, which suggests that statistical significance tests cannot be applied for continuous variables. Among patients with cesarean section, 25.9% had a gestational age of less than 38 weeks. Of patients with less than 38 weeks gestational age (n=14), 85.7% were under 36 years of age, and 50% came from urban areas. Of patients with more than 38 weeks of pregnancy (n=40), 80% were under 36 years of age (p=0.488), and 70% came from urban areas (p=0.153). Gestational age 1-2 pregnancies were recorded by 57.1% of patients with cesarean section at gestational age below 38 weeks and 85% of those with gestational age above 38 weeks (p=0.041). In the case series studied, parity was indirectly correlated, reduced in intensity, with gestational age, but statistically insignificant (r = -0.188 and p = 0.174).

Newborn weight at birth. In patients with cesarean section, the series of values of the child's weight at birth varies in the range of 1,330-4,530 g; group average 3,237 g ± 581.33; median 3,320 g; the result of the Kurtosis test is 2.311 and p<0.05 for the Kolmogorov-Smirnov test, which suggests that statistical significance tests cannot be applied for continuous variables. Among the patients with cesarean section, 50% gave birth to children weighing less than 3320 grams (50th percentile). Birth weight below 3320 g was evident in 50% of the patients with cesarean section (n=27), of which 88.9% were under 36 years of age, 59.3% came from urban areas and 76.9% had less than 3 pregnancies.

Among patients with newborns with a birth weight of over 3,320 g (n=27), 77.8% were under 36 years of age (p=0.234), 70.4% came from urban areas (p=0.285) and 77.8% had less than 3 pregnancies

(p=0.599). Gestational age below 38 weeks was recorded in 42.3% of patients with newborns weighing less than 3320 g and 88.9% of those with newborns weighing more than 3320 grams (p=0.011).The Apgar score was slightly lower in patients under 36 years of age (8.33 *vs.* 8.67; p=0.346), from rural areas (8.16 *vs.* 8.51; p=0.195), with 3 or more pregnancies (8.08 *vs.* 8.46; p=0.234), in mothers with newborns weighing less than 3320 g (8.30 *vs.* 8.48; p=0.484).

The only statistically significant correlation was a reduced Apgar score at gestational age less than 38 weeks of gestation (7.71 *vs.* 8.62; p=0.002)

Total number of days of hospitalization, preoperative and postoperative. In patients with surgical intervention such as cesarean section, the series of values for the number of days of hospitalization varies in the range of 1-22 days; group average 5.75 days ± 3.19; median 5 days; Kurtosis test result 12.289 and p<0.05 for the Kolmogorov-Smirnov test, which suggests that statistical significance tests for continuous variables cannot be applied. 64.4% of the patients in the present study group were hospitalized for less than 5 days, and 5.8% of them for more than 10 days, including both preoperative and postoperative days. Associated medical pathology. Among the associated pathologies, associated fetal risk factors such as umbilical cord circulation of the fetus, presented an estimated 2-fold increased risk of cesarean section (RR=2.0; CI 95%: 1.65-2.42; p=0.036). Relatively higher risk for cesarean section was the presence of diabetes mellitus (RR=1.46; 95% CI: 0.81-2.84; p=0.344), hereditary thrombophilia diagnosed antenatally (RR=1.40; 95% CI: 0.85-2.32; p=0.258), or assisted human reproduction procedures IVF (RR=1.29; 95% CI: 0.57-2.92; p=0.534), but the results cannot be extrapolated to the general population (p>0.05).

Pain study using the VAS scale

VAS score. In the study group, the series of VAS score values vary in the range 1-6; group mean 2.42 ± 1.28; median 2; the result of the Kurtosis test -0.505 and p>0.05 in the Kolmogorov-Smirnov test, which suggests that statistical significance tests can be applied for continuous variables. The VAS score was directly correlated, moderately in intensity, with the patient's age, statistically significant (r= +0.353; p=0.001), which suggests that in 35.3% of patients, higher VAS values were found at older ages. The average VAS values were slightly higher in patients from urban areas (2.49 *vs. 2*.26; p=0.389). The lowest average VAS value was recorded in patients with predominantly classical uterine myomectomy, but also laparoscopic (1.50±0.71; p=0.001) and in the intervention type cesarean section (1.88±1.09; p=0.001), and the highest VAS score in patients with Madden radical mastectomy (3.50±0.71; p=0.001) and HT+AB (3.25±1.39; p=0.001)

DISCUSSION

With the increase in the number of surgical interventions worldwide, but the decrease in the global birth rate, the medicalization of births has occurred and has become an increasingly frequently used practice. Reducing pain during natural births is possible with locoregional anesthesia, with epidural anesthesia in over 60% of births in countries such as Ireland and France, and reducing the risks associated with natural birth by performing scheduled cesarean-type interventions at 38-39 weeks of gestation (12). Pain reduction during natural births is possible with locoregional anesthesia, with epidural anesthesia in over 60% of births in countries such as Ireland and France (13), and the reduction of risks associated with natural births by perform-

ing scheduled cesarean sections at 38-39 weeks of gestation (14).

In a study with data from the Nation Perinatal Survey (*Enquête Nationale Périnatale*), a cross-sectional, nationwide, population-based study conducted in France in March 2021, the frequency and risk factors for acute pain during vaginal birth with epidural analgesia were analyzed. Women who gave birth vaginally with epidural analgesia were included. The intensity of acute pain at the time of delivery was assessed using a numerical pain rating scale from 0 (no pain) to 10 (unbearable pain) and classified into 3 groups: no pain/mild pain (0-3), moderate pain (4-6), or severe pain (7-10). Of these patients, 16.9% experienced moderate pain and 31.4% severe pain at the time of delivery. Independent risk factors for severe pain were maternal age < 25 years, overweight / obesity, prolonged pushing efforts, first or second-degree tears, short or long duration of epidural analgesia, self-reported partially effective or ineffective epidural analgesia, and failure to attend obstetric care or consult a temporary anesthetist. Severe pain was more likely to be experienced in nulliparous women with operative delivery compared with nulliparous women with spontaneous delivery. Maternal age ≥ 35 years, education ≥ 5 years after graduation, and use of PCEA were protective factors for severe pain. Therefore, the conclusions show that one in six women reported moderate pain, and the risk factors were the same as for severe pain, with the exception of obesity, first or second-degree tears, operative birth in nulliparous women, and temporary anesthetists.

The pain perception mechanisms are formed by complex interactions occurring in the dorsal horn between afferent neurons, interneurons, and descending modulatory pathways. These interactions determine the activity of secondary afferent neurons. Glycine and gamma-aminobutyric acid (GABA) are important neurotransmitters that act on inhibitory interneurons (15).

Inhibition of pain transmission says that there are mechanisms that act to inhibit pain transmission at the spinal cord level and by descending inhibition from higher centers. Pain control theory (Melzack, Wall, 1965) describes a process of inhibitory modulation of pain at the spinal cord level (14). It helps explain why when we hit our head, we feel better when we rub it. By activating Aβ fibers with non-noxious tactile stimuli, inhibitory interneurons in the dorsal horn are activated, leading to inhibition of pain signals transmitted via C fibers. Transcutaneous electrical nerve stimulation (TENS) is based on the gate control theory. Stimulation of large-diameter afferent nerve fibers by cutaneous electrodes activates inhibitory processes in the dorsal horn and inhibits pain transmission via C fibers.

The Role of Inflammation in Pain.

A complex interplay between the various biological responses of the immune system, the autonomic nervous system, vascular regulation, and the central and peripheral nervous systems in response to tissue injury, pathogens, and irritants comprises the sensation of pain by the body. Pain can then play a vital protective role for an organism, as is the case with acute inflammation that results in the perception of pain, leading to avoidance of noxious stimuli and encouraging healing of damaged tissue (16).

Inflammatory mediators, produced during inflammation, evoke pain by directly activating and sensitizing nociceptors. Inflammation sensitizes nociceptors (pain-sensitive neurons), leading to increased pain perception. Inflammatory mediators, such as prostaglandins and cytokines, di-

rectly activate nociceptors (7). Pain during caesarean section has potential for later consequences. In the UK, pain during caesarean section was the most common cause of litigation related to obstetric anesthesia care. Pain during caesarean section was described by an obstetric anesthetist from the perspective of a patient who experienced pain and offered ideas for improving practice (17). Significant pain during caesarean section can affect the patient's experience and has been associated as an independent risk factor for postpartum posttraumatic stress disorder (PTSD). According to the American Society of Anesthesiologists (ASA), neuraxial anesthesia for cesarean delivery is generally considered the preferred method of anesthesia, being used for over 95% of elective and 80% of emergency cesarean deliveries in the United States (18). Although highly reliable, neuraxial techniques may be inadequate or may not provide complete surgical anesthesia. Pain during cesarean delivery can be managed by supplementing neuraxial anesthesia, intravenous or inhalational analgesia/anesthesia, or conversion to general anesthesia (19, 20).

CONCLUSIONS

Overall, the analgesic protocol we followed had a satisfactory impact on pain management.

Some discrepancies between patient satisfaction by VAS score assessment and patient perception by qualitative assessment suggest the need for an in-depth qualitative assessment for better pain control. The International Association for the Study of Pain (IASP) defines pain as "an unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage". Therefore, it can be expected that assessing postoperative pain using negatively valanced communications will negatively affect the patient's perceptions of her postoperative experience. Postoperative pain management requires accurate and reliable assessment methods, performed regularly and continuously. Although more outcome measures are needed to adequately capture the complexity of the pain experience, in clinical practice, the use of pain assessment techniques shows that simple scales such as the visual analog scale (VAS) score or the verbal numeric rating score (VNRS) are useful for current practice.

In the postoperative context, the patient's functional capacity can also be assessed using the VAS for pain at rest (static) and with movement (dynamic). The lower the score, the faster the immediate recovery, the earlier the patient's mobilization, in the case of cesarean section, the greater the possibility of caring for the newborn, the establishment of lactation, and for gynecological interventions, the reduced incidence of postoperative complications, namely the resumption of vital organ function, intestinal peristalsis, and the decrease in postoperative headache. There is no "gold standard" for postoperative pain management. Choices are determined in part by drug availability, individual preferences, resource limitations, and financial considerations, and are largely based on opioids, supplemented with anti-inflammatory analgesics, nerve blocks, or other adjunctive techniques. Post-cesarean section pain, resulting from surgical tissue damage, is a major cause of patient dissatisfaction and must be addressed seriously to enable mothers to recover rapidly from a functional standpoint and optimize the early stages of mother-infant interaction. Acute post-cesarean section pain, if not adequately controlled, is associated with prolonged hospitalization, increased costs, and the incidence of chronic pain. Ade-

quate management of post-cesarean pain remains a challenge in the hospital. Better interprofessional collaboration, self-administered analgesia, scheduled medical prescriptions and increased availability of analgesic medications may contribute to improving postoperative pain management, with better pain scores.

CONFLICT OF INTEREST AND FUNDING

MULTIFACTORIAL ANALYSIS OF MALIGNANT ASCITES: ETIOLOGICAL FACTORS AND PROGNOSTIC DETERMINANTS IN A LARGE HOSPITAL COHORT (Abstract): Carcinomatous ascites is a manifestation of advanced-stage disease that can arise from various malignancies, most commonly digestive cancers. This study analyzes the impact of ascites development on disease progression, survival outcomes and several prognostic factors. **Materials and methods**: This is an observational and retrospective study of 1,470 patients diagnosed with ascites, irrespective of etiology, admitted to the Gastroenterology and Internal Medicine Clinic of Sf. Ioan Clinical and Emergency Hospital Bucharest, a Romanian Tertiary Hospital, during 2015-2023. This study aimed to provide a comprehensive statistical analysis of patient characteristics and etiological factors associated with ascites, focusing on malignant ascites. **Results:** Malignant ascites was identified in approximately 10% of patients with ascites and was significantly more frequent in association with digestive malignancies compared with extradigestive tumors. Tumors of digestive origin-particularly hepatic cancers-was markedly more often associated with ascites, while extradigestive neoplasms showed a substantially lower incidence. The presence of ascites was strongly associated with malignancy, patients with ascites having a significantly higher prevalence of cancer compared with those without ascites. **Conclusions:** The findings regarding patients with malignant ascites were contextualized considering local patterns of disease etiology, which may influence prognosis and clinical outcomes. **Keywords:** CARCINOMATOUS ASCITES, DIGESTIVE MALIGNANCY, EXTRADIGESTIVE NEOPLASIA.

INTRODUCTION

Ascites is the pathological accumulation of peritoneal fluid, most commonly occurring as a consequence of hepatic cirrhosis complicated with portal hypertension (1, 2). The onset of ascites in chronic liver disease reflects disease progression and is associated with unfavorable outcomes, increased mortality, and the development of major complications with a negative impact on survival, including hepatorenal syndrome, spontaneous bacterial peritonitis, and hydrothorax (3, 4, 5). Approximately 5-10% patients with compensated liver cirrhosis develop ascites per year, that reduces the overall 5-year survival from 80% to 30% (6). In liver cirrhosis, multiple mechanisms are responsible for ascites

development, most important being portal hypertension with splanchnic arterial vasodilation and lymph hyperproduction (7, 8, 9).

Advanced liver disease is often accompanied by severe cytopenia especially thrombocytopenia due to portal hypertension. A minimally invasive technique, that is partial splenic embolization has been designed in order to reverse this issue. A rare complication of this procedure is spleno-portal axis thrombosis with ascites development (10).

Malignant ascites is defined by accumulation of peritoneal fluid with atypical cells and represents a complex entity that encompasses several illnesses, both digestive and extradigestive neoplasms. Different mechanisms have been proposed regarding the ascites that accompanies abdominal tumors. Approximately 10% of patients exhibit characteristics of malignant ascites, with peritoneal metastasis due to an underlying cancer, usually ovarian or breast cancer, as well as neoplastic disease of digestive origin - gastric, colonic, appendix, biliary tract or pancreas (1). The peritoneal fluid accumulation is caused by obstruction of lymphatic vessels and enhanced vascular permeability due to inflammation which is typical for a neoplastic process (11, 12). Lymphatic obstruction was recognized as a major factor in malignant ascites pathogenesis since 1953 when Holm-Nelson injected India Ink into the peritoneal cavity of mice with malignant ascites and observed that the substance remained into the peritoneal cavity (13, 14).

It is well known that abdominal tumors induce an inflammatory response in the abdominal cavity that facilitates adhesion of malignant cells to peritoneum and carcinomatosis development (12, 15). Malignant ascitic fluid shows high protein level, elevated LDH and low SAAG. The cytological examination of ascitic fluid is not always diagnostic; a negative result does not exclude a neoplastic etiology (11).

A totally different mechanism is seen in ascites that accompanies abdominal tumors. Abdominal neoplasia can lead to the development of ascites through direct tumor invasion of the portal venous system, portal vein thrombosis, or mass effect from tumor bulk, even when the ascitic fluid does not contain malignant cells (11, 16).

Regarding peritoneal carcinomatosis due to intraabdominal tumors, the most frequent neoplasia associated with peritoneal carcinomatosis is ovarian cancer.

The process of carcinomatosis development is initiated by cell exfoliation from primary tumor, followed by their migration into the peritoneal cavity and adhesion of epithelial ovarian cells to mesothelial peritoneum cells and underlying stroma (17, 18, 19). Ascites formation along with carcinomatosis carries the worst prognostic in terms of disease progressions, recurrence and survival (20, 21). Ovarian cancer is the six most common cause of female cancer, the second most frequent gynecological malignancy in Western countries and the most common cancer related death in women, with a low survival rate of 39% at 5 years (18, 22, 23). Almost 70% percent of patients have advanced disease at diagnosis, that is stage III-IV and exhibit peritoneal dissemination (23, 24). Peritoneal metastasis requires a thorough assessment, using cutting-edge imaging methods FDG PET /CT, CT and PET MRI, that allow to establish the disease extent and guide the subsequent therapeutic management (25). In this particular condition, glycoprotein

CA 125 which is widely recognized as a tumoral marker for ovarian cancer, is also synthesized by peritoneum mesothelial cells, independent of malignant etiology, due to the pressure of ascitic fluid exerted on the mesothelial lining (26).

Another malignancy with well-known peritoneal involvement is gastric cancer. Peritoneal carcinomatosis is associated with poor prognosis and a significant decrease in survival rate, the median survival ranging from 2 to 9 months (27, 28).

Malignant ascites is found in 18 % of patients with gastric cancer and rarely represents the presenting symptom at the time of diagnosis (29). Risk factors for peritoneal involvement in gastric cancer are related to cancer stage, age, invasion depth and tumor location, cardia and gastric corpus tumors having high risk of peritoneal dissemination (30). Generally, malignant ascites develops in the advanced stages of gastric tumor and is typically seen as a late manifestation of disease, accompanied by an altered clinical status (31).

Colorectal cancer remains a major public health concern despite the significant progress achieved in early detection through screening programmes. It accounts for aproximately10% of worldwide neoplasms, with 25% of cases being discovered only at metastatic stage (32).

Among these, colorectal tumor with peritoneal metastases represents an advanced and challenging condition associated with a poor prognosis. The most frequent histological subtypes are mucinous adenocarcinoma and signet ring cell carcinoma, both characterized by aggressive behavior and low survival rates compared to non-mucinous forms. An essential diagnostic tool in the evaluation of these tumors is immunohistochemistry, which allows an accurate tumor classification and guides the therapeutical management (33). Its utility has been well established over the time, demonstrating its ability to identify neoplasms with high potential for dissemination and unfavorable clinical outcomes, including peritoneal metastases (34, 35).

Carcinomatous ascites is commonly encountered in elderly patients, who often present with multiple underlying pathologies, including various malignancies, abdominal metastatic disease or peritoneal carcinomatosis from un unknown primary neoplasm (37, 38). In clinical settings, a common scenario consists of substantial abdominal fluid accumulation, reflecting tumor dissemination and peritoneal involvement. A comprehensive diagnostic work-up is essential to evaluate the extent of neoplastic spread and to determine the primary tumor origin, most commonly within the gastrointestinal or gynecologic tract (39).

MATERIALS AND METHODS

This retrospective study analyzed 13,264 patients from consecutive admissions to the Gastroenterology and Internal Medicine Clinic of Sf. Ioan Emergency Hospital over an eight-year period, from 2015 to 2023.

Out of this study population of 13,264 hospitalizations, 1,470 patients (11.1%) were diagnosed with ascites and constituted *the primary study cohort.* Our unit can provide several diagnostic and interventional procedures, such as emergency endoscopy and partial splenic embolization for hypersplenism secondary to liver cirrhosis. Gastroenterology and Internal Medicine wards were analyzed together due to overlapping clinical conditions. The purpose of this study was to systematically

evaluate the demographic and clinical characteristics of patients with ascites and to analyze the underlying etiological factors, with particular emphasis on the patterns and features associated with malignant ascites.

RESULTS

The results are organized into two main parts. The first provides a general overview of the entire study population, based on all hospital admissions (n = 13,264), which serves as the reference population. The second part presents a more detailed analysis focusing specifically on patients diagnosed with ascites (n = 1,470).

Baseline ward population. It is important to note that all age decades were represented in the study population, ranging from adolescents to very elderly patients, including individuals over 100 years of age.

TABLE I.

Distribution of ascites according to age decade and gender

Age group	Female			Male			Overview 2015-2023		
	Ascites	Non-Ascites	Total Female	Ascites	Non-Ascites	Total Male	Ascites	Non-Ascites	Total
10-19 years	0	8	8	0	16	16	0	24	24
20-29 years	2	129	131	4	122	126	6	251	257
30-39 years	6	182	188	43	246	289	49	428	477
40-49 years	47	444	491	140	602	742	187	1.046	1.233
50-59 years	77	769	846	263	895	1.158	340	1.664	2.004
60-69 years	172	1.474	1.646	349	1.629	1.978	521	3.103	3.624
70-79 years	105	1.563	1.668	148	1.272	1.420	253	2.835	3.088
80-89 years	73	1.264	1.337	31	844	875	104	2.108	2.212
90-99 years	5	203	208	5	128	133	10	331	341
Over 100 years	0	1	1	0	3	3	0	4	4
Total	**487**	**6.037**	**6.524**	**983**	**5.757**	**6.740**	**1.470**	**11.794**	**13.264**

Characteristics of patients with ascites

Age comparison. Regarding the study cohort of 1,470 diagnosed with ascites, the prevalence with ascites is not uniformly distributed across age groups; the curve demonstrates a more pronounced occurrence in midlife. Ascites showed a clear age-related distribution. No cases were identified among adolescents aged 10-19 years, suggesting that ascites is exceedingly rare in this age range in the present cohort, while only 2.3% of patients in the 20-29 age group presented with ascitic fluid. In contrast, a sharp increase was observed beginning with the 30-39 age group, in which the prevalence rose more than fourfold to 10.3%. This upward trend continued into the subsequent decades, with the highest prevalence observed in patients aged 50-59 years, at approximately 17%, indicating that nearly one

in six hospitalized individuals in this age range had ascites. Beyond the age of 60 years, the prevalence declined gradually, decreasing to 14% in the 60-69 age group, 8.2% in patients aged 70-79 years, and falling below 5% in the subsequent decades, with values of 4.7% in patients aged 80-89 years and 2.9% in those aged 90-99 years, reflecting a clear reduction in ascites prevalence at advanced ages.

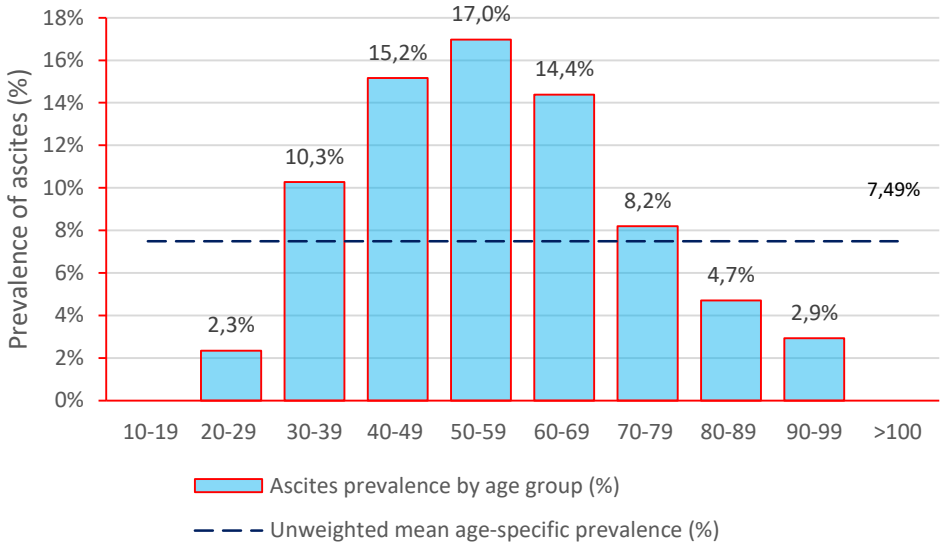

Fig 1. Prevalence of ascites by age groups

Considering all ten age groups as a whole, the mean prevalence is 7.5%, while the dispersion is higher (variation coefficient 85%), confirming that the phenomenon is concentrated around the middle age decade. The chart demonstrates that ascites is not uniformly distributed across age groups but is predominantly a condition affecting middle-aged adults.

Gender comparison. Out of a total of 13,264 hospital admissions, 1,470 patients were diagnosed with ascites. The graphical analysis revealed distinct age- and gender-related patterns in ascites prevalence.

*Male patients***.** From the earliest observable values (approximately 3% in men aged 20-29 years), prevalence increased markedly to 15% in men aged 30-39 years, reaching an absolute peak in the 50-59 decade at approximately 23%, corresponding to nearly one in four male patients.

Overall, men accounted for nearly two-thirds of all ascites cases in the database (983 out of 1,470; 66.8%).

*Female patients***.** In women, prevalence was approximately 2% in the 20-29 age group and increased to around 9-10% across the 40-69 age decades, without exceeding the overall threshold of 11%. The female peak occurred in the 60-69 age group (approximately 10%), remaining about seven percentage points lower than that observed in men of the same age. After the age of 70 years, prevalence in both genders declined and the gap narrowed. In the 70-79 age group, prevalence decreased

to approximately 10% in men and 6% in women. In the 80-89-decade, prevalence among men fell below 4%, while women maintained a prevalence of around 5-6%. In patients aged over 90 years, ascites prevalence dropped below 4% in both genders.

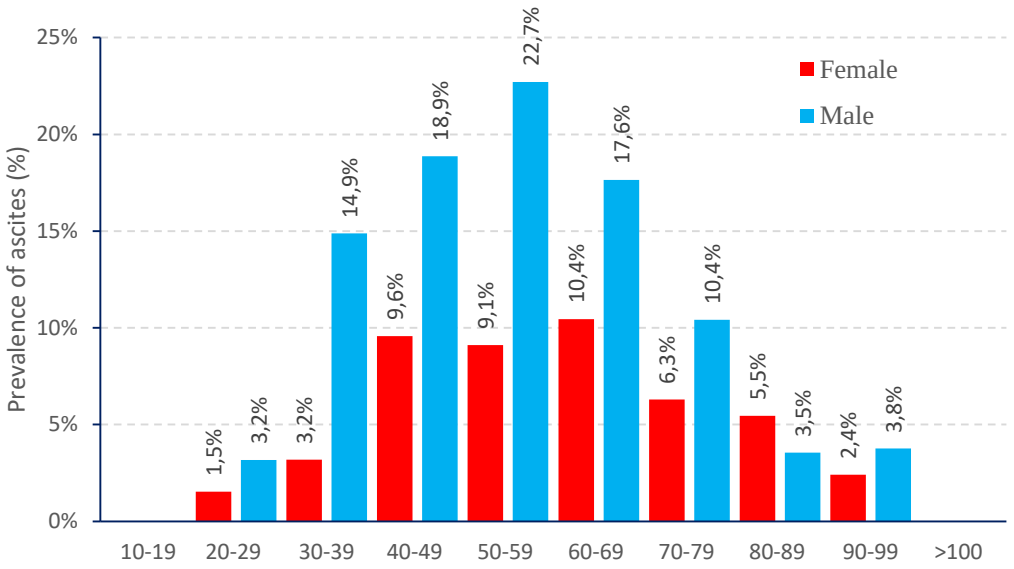

Fig. 2. Prevalence of ascites by gender and age groups

At first glance, the data suggest that men develop ascites more frequently than women: despite a nearly equal number of hospital admissions for each sex, the number of male ascites cases is approximately double from that observed in females. However, to formally confirm this observation, a chi-square (χ^2) statistical test is required, as it assesses the association between the two categorical variables-gender and the presence of ascites.

The following hypotheses were formulated: the null hypothesis (H_0) states that the gender distribution is the same among patients with ascites and those without ascites, whereas the alternative hypothesis (H_1) assumes that the gender distribution differs between the two groups. If the statistical test rejects the hypothesis that gender and ascites are independent, this would indicate that gender should be considered a relevant factor in the clinical interpretation of ascites.

TABLE II.
Gender-specific distribution of ascites and non-ascites cases

Gender	Ascites	No Ascites	Total
Female	487	6.037	6.524
Male	983	5.757	6.740
Total	**1.470**	**11.794**	**13.264**

The chi-square test of independence showed a statistically significant association between gender and the presence of ascites (χ^2 (1) = 169,81, p ≈ 8,14 × 10^{-39}).

Since the p-value is below the conventional significance threshold of 0.05, the null hypothesis is rejected, indicating a statistically significant difference in gender distribution between patients with ascites and those without ascites.

The hospital admitted nearly equal numbers of men and women (6,740 and 6,524, respectively). However, among patients with ascites, the distribution was markedly skewed toward men, with 983 male cases compared with 487 female cases. When expressed as proportions, 14.6% of men developed ascites, compared with 7.5% of women, corresponding to an almost 2: 1 ratio.

The statistical analysis confirms this observation: male gender is strongly associated with the presence of ascites, indicating that the observed difference is not due to random variation but reflects a genuine risk factor.

TABLE III.
In-hospital outcomes by ascites status

Ascites / Non-Ascites	Discharged	Deceased	Transferred	Total
Patients with Ascites	912	489	69	1.470
Patients without Ascites	9.582	1.871	341	11.794
Total	**10.494**	**2.360**	**410**	**13.264**

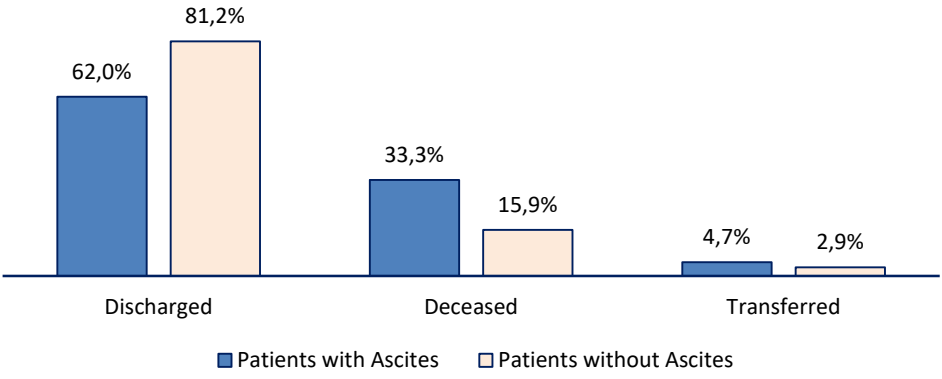

Fig. 3. In-hospital outcomes by ascites status (%)

The outcome profile differs markedly between patients with and without ascites. As illustrated in the chart, the discharge rate was substantially lower among patients with ascites (62%) compared with those without ascites (81.2%). Conversely, in-hospital mortality was notably higher in the ascites group (33.3%) than in the non-ascites group (15.9%), indicating a less favorable clinical course for patients presenting with ascites.

Transfers were uncommon in both groups but occurred slightly more frequently among patients with ascites (4.7% *vs.* 2.9%).

Overall, these findings suggest that ascites is associated with worse short-term hospital outcomes, characterized by a lower likelihood of discharge and a higher risk of in-hospital death. This pattern is consistent with ascites being a marker of more advanced disease and greater clinical severity; however, these observations are descriptive and do not establish causality or account for potential differences in baseline risk between the two groups.

Statistical analysis of patients with ascites and underlying etiologies. This analysis evaluates the association between the presence of ascites and the existence of a malignant tumor. Ascites may have multiple causes; however, in an oncological context, it often represents a secondary manifestation of tumor dissemination or a consequence of tumor-related pathophysiological processes. Identifying the frequency of malignant tumors in patients with ascites contributes to understanding the significance of ascites as a clinical indicator in the differential diagnosis.

TABLE IV.
Association between ascites and tumor status

Ascites status	No malignancy	Malignancy present	Total
YES	1.154	316	1.470
No	10.329	1.465	11.794
Total	**11.483**	**1.781**	**13.264**

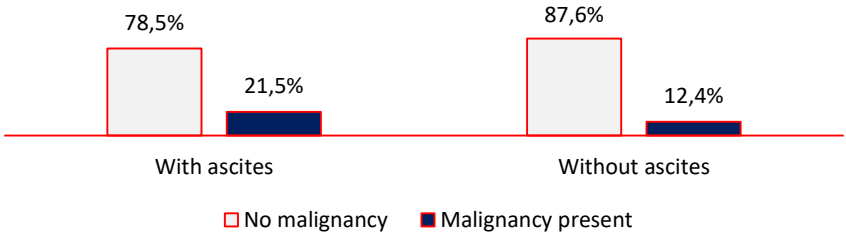

Fig. 4. Malignancy status according to ascites presence

In the analyzed cohort (n = 13,264 patients), ascites was present in 1,470 patients (11.1%). Among these, 316 patients (21.5%), had a prior diagnosis of a malignant tumor, compared to only 12.4% of patients without ascites who had a known neoplasia. The results indicated a significant statistical association between the presence of ascites and tumor status.

Patients with ascites had a prevalence of malignant tumors of 21.5%, compared to 12.4% among those without ascites. This difference of 9.1 percentage points is supported by high values of risk indicators:

- Relative risk (RR = 1.73): patients with ascites have a 73% higher risk of having a malignant tumor.
- Odds ratio (OR = 1.93): the likelihood

of an association between ascites and cancer is nearly doubled.

• Chi-square test (χ^2, 1 df = 92.6; $p < 0.0001$): confirms the statistical significance of this relationship.

These results support the hypothesis that ascites represents an important clinical sign suggestive of an underlying malignancy, particularly in the absence of obvious hepatic causes. Therefore, patients presenting with ascites of unclear etiology should undergo further oncologic and imaging investigations.

TABLE V.

Estimation of the Risk of Malignancy Associated with the Presence of Ascites

Indicator	Value	Confidence Interval 95%
Proportion of cancer patients with ascites	21.50%	19.4% - 23.6%
Proportion of cancer patients without ascites	12.40%	11.8% - 13.0%
Absolute difference	+9.1 pp	—
Relative risk (RR)	1.73	1.55 - 1.93
Odds ratio (OR)	1.93	1.69 - 2.21
Chi-square test (χ^2, one degree of freedom)	≈ 92.6	$p < 0.0001$

Comparison between digestive and extradigestive malignant tumors associated with ascites

The present analysis included a total of 13,264 clinical cases, of which 1,470 patients presented with ascites and 11,794 did not exhibit this feature at the time of evaluation. Within this cohort, 28 distinct types of malignant tumors were identified and classified as digestive or extradigestive malignancies according to anatomical and functional criteria, based on the World Health Organization (WHO) and European Society for Medical Oncology (ESMO) guidelines from the 2020-2025 period. Among the analyzed cases, 2,823 records corresponded to patients with confirmed malignant tumors, forming the database used for the detailed analysis of the relationship between tumor localization and the presence of ascites.

Of these, 1,105 were classified as digestive malignancies and 1,718 as extradigestive malignancies, according to the classifications mentioned above.

This classification includes neoplasms of the digestive tract proper (esophagus, stomach, colon, rectum) as well as those arising from other digestive structures (liver, biliary tract, pancreas, peritoneum), in contrast to tumors originating from other systems - lymphatic, respiratory, urinary, endocrine, nervous, or reproductive. Within these two categories, each of the 28 tumor types was evaluated according to the presence or absence of ascites to determine the etiology of malignant ascites. Tumors of digestive origin (blue) were much more frequently associated with ascites, whereas extradigestive tumors (red) exhibited a substantially lower incidence (fig. 5). The highest proportions of ascites were observed in hepatic cancer (52.0%) and peritoneal carcinomatosis, a condition characterized by the dissemination of tumor cells on the peritoneal surfaces (44,4%), with lower rates in pancreatic cancer (29.1%) and liver metastases (19.3%), these conditions representing the main causes of malignant ascites in the studied cohort.

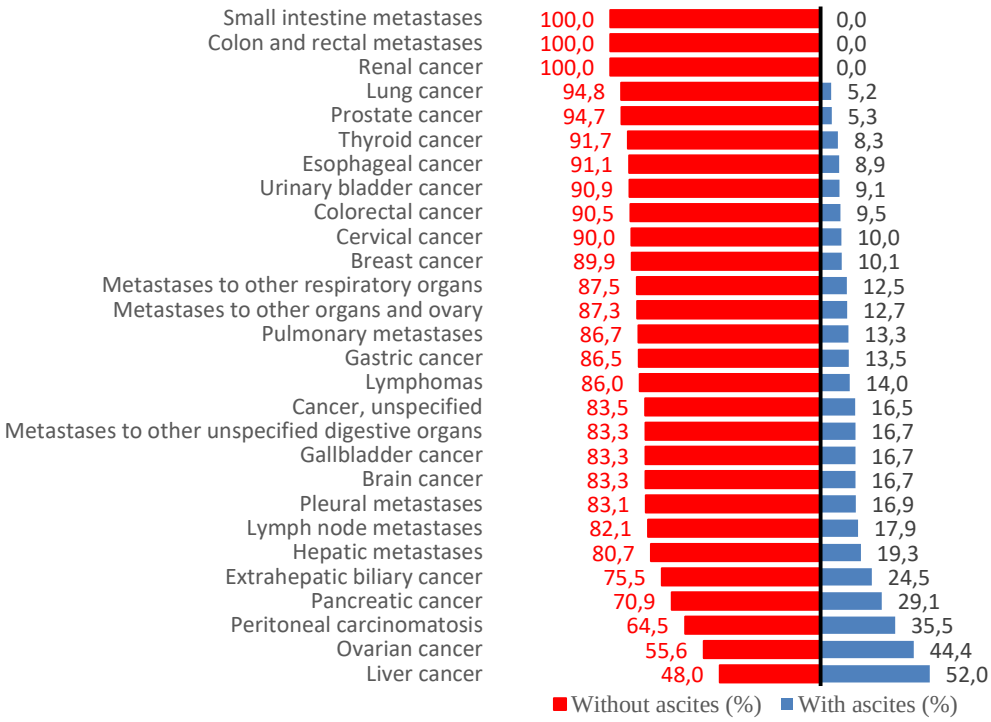

Fig. 5. Distribution of patients without ascites according to the type of malignant tumor

In comparison, extradigestive tumors, such as lung cancer, breast cancer, lymphomas, or ovarian metastases, had a minor involvement (<10%), confirming that malignant ascites is predominantly associated with abdominal neoplasms and only occasionally with systemic or extradigestive tumors.

The differences observed between the two groups (digestive *vs.* extradigestive) reflect distinct pathophysiological mechanisms. In digestive tumors, ascites typically develops as a result of portal obstruction, hepatic invasion, or peritoneal dissemination-mechanisms that promote the accumulation of fluid in the abdominal cavity. In contrast, in extradigestive tumors, ascites usually occurs secondarily and is associated with extensive metastases or widespread lymphatic involvement.

This initial visual and descriptive analysis provided a clear framework for testing statistical hypotheses regarding the association between tumor type and the presence of ascites, which will be explored in detail in the subsequent section. To evaluate the relationship between malignant tumor localization and the development of ascites, a comparative analysis was performed between the two main groups: digestive and extradigestive malignancies.

The difference between the initially reported total of 2,823 oncological records and the 2,261 records included in the final statistical analysis (tab. VI) resulted from a rigorous data selection process. To ensure the validity of statistical testing (including the chi-square test and the calculation of

relative risk) and to minimize potential confounding, the following criteria were applied:

- *Inclusion criteria*: only records with a single, clearly defined tumor localization-either strictly digestive or strictly extradigestive-were retained.
- *Exclusion criteria*: a total of 562 records with concomitant tumor localizations (both digestive and extradigestive) were excluded.

This approach was necessary because the simultaneous presence of both tumor types would have precluded the precise attribution of ascites to a specific tumor category. Consequently, the analysis was performed at the level of oncological records, ensuring statistical independence between the two comparison groups and allowing for reliable estimation of risk indicators, including relative risk (RR) and odds ratio (OR).

For this purpose, 2,261 oncological records corresponding to patients diagnosed with digestive and extradigestive malignant tumors were included. As some patients presented simultaneously with tumors of both types, the analysis was conducted at the level of tumor records rather than individual patients, in order to accurately capture the distribution according to tumor localization.

TABLE VI.

Distribution of Malignant Tumor Records by Tumor Type and Ascites Status

Tumor Type	With ascites	Without ascites	Total
Digestive	267	837	1.104
Extradigestive	150	1.007	1.157
Total	**417**	**1.844**	**2.261**

The results show that ascites was present in 24.2% of patients with digestive malignancies, compared with 13.0% of those with extradigestive tumors. This statistically significant difference (χ^2 = 36.8; $p < 0.001$) indicates a clear association between digestive tumor origin and the development of ascites.

To quantify this risk, the following measures were calculated:

- Relative risk (RR = 1.86): patients with digestive malignancies have an almost twofold higher risk of developing ascites compared with those with extradigestive tumors.
- Odds ratio (OR = 2.14): confirming a significantly increased likelihood of ascites in digestive neoplasms.

These findings support the hypothesis that pathogenetic mechanisms involved in digestive tumors-such as portal venous obstruction, hepatic infiltration, portal hypertension, and peritoneal carcinomatosis-promote peritoneal fluid accumulation to a significantly greater extent than in extradigestive malignancies. In contrast, in extradigestive tumors (e.g., lung, breast, lymphatic, or urogenital malignancies), ascites occurs less frequently and generally in advanced stages of disease dissemination, typically through secondary mechanisms such as peritoneal metastases or lymphatic obstruction.

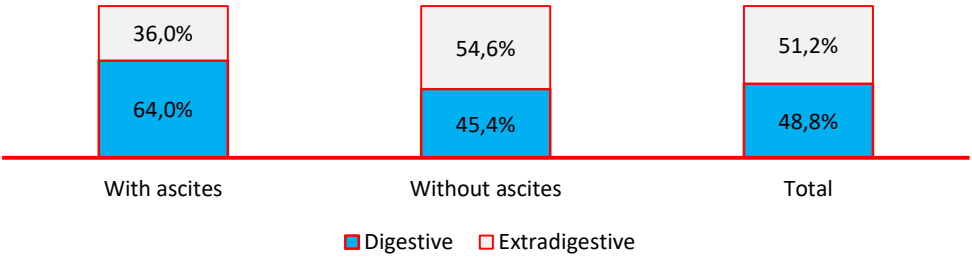

Fig. 6. Percentage Distribution of Digestive *vs.* Extradigestive Malignancies by Ascites Status

Figure 6 highlights the proportional differences between digestive and extradigestive malignant tumors according to the presence of ascites. Of the 417 tumor records associated with ascites, 64.0% corresponded to tumors of digestive origin, whereas only 36.0% were extradigestive. In contrast, among the 1,844 cases without ascites, the distribution was reversed: 54.6% of tumors were extradigestive and 45.4% were digestive. Overall, within the entire dataset of 2,261 tumor records, the distribution was relatively balanced, with 48.8% digestive and 51.2% extradigestive malignancies. However, this balance changed markedly when ascites status was considered, indicating a clear association between digestive tumor localization and the presence of ascites. This observation is consistent with the results of the statistical analysis ($\chi^2 = 36.8$; $p < 0.001$), confirming that malignant ascites occurs significantly more frequently in tumors of digestive origin.

DISCUSSION

Malignant ascites is defined as the accumulation of peritoneal fluid containing malignant or atypical cells and represents a complex clinical entity associated with a wide spectrum of underlying diseases. It occurs in the context of both digestive and extra-digestive malignancies and is typically indicative of advanced-stage disease. The development of malignant ascites reflects multifactorial pathophysiological mechanisms, including peritoneal carcinomatosis, increased vascular permeability, lymphatic obstruction, and tumor-related inflammatory processes (11, 17, 18). Its presence is often associated with significant morbidity and carries important diagnostic, therapeutic, and prognostic implications (23, 24). Benign ascites typically develops in patients with non-malignant conditions such as liver cirrhosis with portal hypertension and is not associated with the presence of cancer or malignant cells in the ascitic fluid. A new clinical entity has been described, referring to the development of ascites in patients with neoplastic disease in the absence of detectable tumor cells in the peritoneal fluid, termed para malignant ascites (11). The clinical presentation of ascites also varies according to patient demographics and underlying disease. Significant differences between genders were observed among patients with ascites. Liver cirrhosis and its main complication, hepatocarcinoma, occur predominantly in men, reflecting the higher prevalence of hepatic risk factors in the male

population. Patient age varies according to the underlying disease: cirrhotic ascites typically occurs in patients around 60 years of age, whereas malignant ascites occurs in older patients (approximately 70 years). Generally, most patients with ascites have it secondary to chronic liver disease, while malignant ascites accounts for nearly 10% of cases, consistent with previously published data (8, 41, 42, 43). Ascites was significantly more frequent in tumors of digestive origin, particularly hepatic cancers and peritoneal carcinomatosis, whereas tumors of extradigestive origin were rarely associated with ascites. On the other hand, abdominal metastatic disease-particularly liver metastases of various origins-showed a lower incidence of peritoneal fluid accumulation. Some authors have reported ovarian cancer as the most frequent cause of malignant ascites development (16). This finding, however, is not consistent with our data, which may reflect the specific patient population of our clinic, where digestive diseases predominate. It is important to consider the limitations of our study when interpreting these results. In particular, the specificity of our department does not encompass the full spectrum of malignancies that can cause ascites, and therefore our findings may not provide a comprehensive perspective on all ascitic etiologies and may not be generalizable to all patient populations.The predominance of abdominal and digestive tumors in our clinic likely influenced the observed distribution of ascites, potentially underrepresenting conditions, such as ovarian or systemic cancers, which are reported elsewhere as common causes of malignant ascites. Recognizing this context is essential for accurately interpreting our data and for comparing it with findings from other institutions.

CONCLUSIONS

Ascites is a clinically important manifestation, reflecting significant underlying disease and carrying diagnostic, therapeutic, and prognostic implications. In our cohort, ascites was more frequently associated with digestive malignancies, particularly hepatic cancers and peritoneal carcinomatosis, whereas extradigestive tumors rarely resulted in fluid accumulation. These findings should be interpreted in the context of our clinic's patient population, which predominantly manages digestive diseases; this specificity likely influenced the observed distribution and may underrepresent other malignancies such as ovarian or systemic cancers. Overall, the presence of ascites, whether benign or malignant, serves as an important clinical indicator warranting careful evaluation and targeted management.

ETHICAL AND DEONTOLOGICAL ASPECTS OF PALLIATIVE CARE IN GERIATRIC PATIENTS IN ROMANIA. CASE REPORT (Abstract): We present the case of an 82-year-old female patient with a personal history of hypertension and diabetes, who presented to the emergency room for marked physical asthenia, loss of appetite and diffuse abdominal pain with onset about a week earlier. Recent history showed that she suffered a same-level fall in the past 24 hours, and was unable to get up from the floor where she had laid for several hours. On admission, the patient complained of severe diffuse osteoarticular pain that kept her in bed; she also complained of lower abdominal pain on superficial and deep palpation that proved to be a urinary tract infection. She was dehydrated and anemic (Hb=7.3 g/dL); she was depressed and very anxious to get home as quickly as possible. The therapeutic approach was focused on the prompt correction and the thorough investigation of the severe anemia syndrome, the complex therapy of osteoarticular pain, and prevention of the complications of immobilization syndrome. Despite patient's wish that multiple and complex investigations not to be conducted and to be discharged from the hospital and go home, the family strongly insisted to continue searching, no matter what, for the causes of anemia with the purpose of prolonging her life, but with very poor outcome on patient's quality of life. With no specific laws concerning the respect for patient's wishes, the medical personnel had very little to say in this matter, even if we watched the decline in her quality of life with every day she spent away from home. **Keywords:** PALLIATIVE CARE, ELDERLY AUTONOMY, FAMILY SUPPORT.

In recent years, the dramatic fall in birth rate, along with the aging of the population and the increasing number of chronic patients has led to an increase in the needs for specific care.

In Romania, isolated initiatives draw attention to the continuous increase in the needs for special care to be provided to elderly patients with severe chronic diseases or disabilities who can no longer take care of themselves (1).

While performing the medical act, the medical team must meet the patients' needs to be informed, to be understood, to be respected, to be helped to reduce anxiety, to feel safe, to be independent, to preserve their dignity and finally to help relieve their pain (2).

Autonomy is a person's right to self-determination, independence and freedom. It is not just the right to self-determination and treatment of the body; it also implies the right to receive any information regarding himself/herself, his/her way of life and health, the right to decide to whom some of his/her personal, sacred data can be entrusted; these are an integral part of the meaning of self and identity. Knowing personal information about someone can play an important role in procuring the sense of security, freedom and self-esteem (3).

When the patient refuses treatment or any investigation, it is considered that his will prevails over his health.

The legal framework in Romania (Law No. 46/2003 on the Patient's Right, updated in 2017, Article 13) grants the patients the right to refuse or discontinue medical treatment, assuming responsibility for their decision, in writing, as long as they are well aware and show no loss of judgement (4). In practice, the conduct in such cases is slightly different. Often the caregivers are the ones informed and involved in treatment decisions making in an attempt of either to protect the patient emotionally or due to the pressure (often becoming threats) exerted by caregivers.

CASE REPORT

We present the case of an 82-year-old female patient, living in an urban area with her husband whom she cared for as he was suffering from a major cognitive impairment (vascular dementia), she herself finding it difficult to move around and receiving help from a nurse with some daily activities. She was known to have a history of cardiovascular (hypertension, angina, and degenerative aortic stenosis) and metabolic (type 2 diabetes treated with medication and complicated by peripheral sensory polyneuropathy) diseases, and recurrent urinary tract infections.

She was hospitalized for significant physical asthenia, loss of appetite, diffuse abdominal pain going on for about a week and severe polyarticular pain which did not allow her to move. From her family's (her sister) statements it came out that the patient had suffered a same-level fall 24 hours previously, without the possibility to get up from the floor, where she was found the next day by her caregiver.

At the time of admission, the patient was in altered general condition, conscious, cooperative, with difficulty in moving around due to the post-traumatic pain, dehydrated, with pale skin and multiple bruises on the upper extremities. Cardiovascular examination revealed rhythmic heart sounds, systolic murmur in the aortic outbreak radiating to the carotids, normal blood pressure. Also noted was the abdomen increased in volume due to *panniculus adiposus*, with lower abdominal pain on superficial and deep palpation.

Biochemical findings showed multiple concomitant medical conditions:

a. *Severe anemia syndrome*, normochromic, normocytic (Hb = 7.3 g/dL), non-regenerative (reticulocytes = 11,377/mm^3), with low serum iron and increased ferritin levels. Considering that in evolution we recorded a drop-in hemoglobin of 1.0 g and the presence of blood in her stools, we interpreted it as an episode of melena, possibly due to a digestive cancer. We explained to the patient and her family that an endoscopy (upper and lower) would be required, investigation refused by the patient, but her family strongly pressed for it. Given the mixed nature of the anemia

(malnutrition + inflammatory syndrome), the therapeutic management was complex, targeting the correction of Hb by administering blood transfusion, iron based medication and dietary supplements.

b. *Urinary tract infection* with *Klebsiella pneumoniae*, *Candida spp.*, with multi-resistant germs and unfavorable progression towards sepsis despite the complex antibiotic treatment. During hospital stay, probably due to bed immobilization and diabetic neuropathy, she developed acute urinary retention which required urinary catheterization and highly contributed to the negative development of sepsis and decline in her quality of life and self-esteem.

c. *Fluctuating blood glucose levels* that required the introduction of low doses of insulin with daily adjustments depending on the glucose profile; the inflammatory syndrome and the depressive syndrome of the patient made her refuse food.

d. *Geriatric evaluation* showed that she was at risk of malnutrition (MNA= 23.5/30), with a minor cognitive impairment (MMSE= 25/30), depressed (GDS= 6/16) and highly dependent on the help of a caregiver.

During hospital stay, she remained confined to bed, resisting all attempts to mobilization, even for personal hygiene. However, with patience and persuasion, we managed to prevent the complications of bed immobilization (daily tapotement, permanent linen change, feeding and hydration with the help of medical staff, regular changes of patient position in bed, etc.); however, due to the increased resistance of the patient to any medical care, after approximately two weeks her general condition deteriorated, she became hemodynamically unstable and was admitted to the ICU department, where she required IOT and mechanical ventilation with positive inotropic support. The invasive maneuvers for endotracheal intubation and urethro-vesical catheterization led to sepsis with multiple starting points (urinary tract, lungs, skin) and with multi-resistant bacteria. At that point, the medical geriatric team considered that it was time to consider palliation versus extensive medication. The possibility to choose home care, in her familiar environment might have improved communication and patient compliance with the hygienic, dietary and drug treatment (5). However, due to lack of qualified personnel for home care in Romania and patient's financial limitations, this approach was not an option.

DISCUSSION

Given that autonomy is one of the ethical principles involving the respect for the right of every individual to make their own decisions, the patients' wishes must be complied with if they are of sound mind and they can decide perfectly regarding their last wishes (6).

Thus, the medical staff had to provide the patient with all necessary information for her to make the right decision, to help her understand and apply the decision, in this case being necessary to stop the aggressive investigations and to conduct invasive treatments only with the patient's approval. In our case, the patient had given her consent to continue invasive investigations because of the pressure exerted by her family, but despite her own wishes. The creed of the medical profession is to ensure the highest possible level of quality of life, especially in the case of terminal patients for which medical interventions have no longer a curative purpose.

The decision made freely by the patient should be checked to determine whether it was imposed by another person, especially by the family, who, besides being a support, must also respect his/her wishes.

In the here reported case, the family permanently refused the patient to be discharged from hospital and cared at home and requested, even claimed sometimes, the continuation of all investigations (including CT with contrast substance) and maneuvers (including admission to the intensive care unit where she was intubated and mechanically ventilated), thus negatively influencing her evolution. In addition, the stress placed on the medical team was significant, caused by confrontations with the patient's family on the provision of complex care, without respecting her wish and her privacy (7, 8).

Finally, respecting the patient's autonomy goes hand in hand with human dignity. The law and the society are *pro* patient autonomy as a human right and as a basic principle in the doctor-patient relationship.

CONCLUSIONS

Regardless of the medical decision, the last word belongs to the patient. In our case, despite all efforts to investigate and treat her, the patient wanted to go home, in her familiar environment, to be with her loved ones in the last moments of her life.

The lack of methodology for the enforcement of the laws on patient rights, but also not knowing the components of such laws, makes such situations difficult to manage by the medical staff, situations in which the emotional elements dominate the legal framework, generating the overstepping of attributions and the involuntary exit from this framework.

The fight is between the slogan: *"We did everything humanly possible*", a slogan the family relies on, and the *motto "Respect the wishes of the loved one and who is ready to leave from amongst us*".

CLINICAL CHANGES AND BIOMETRIC DIFFERENCES IN PATIENTS WITH OPEN ANGLE GLAUCOMA AND DIABETES (Abstract). **Aim of study** was to emphasize the clinical changes and biometric alterations that appear in primary open angle glaucoma (POAG) patients if diabetes was associated. **Material and methods:** The study was designed in a cross-sectional manner, between 2015-2016 in the Ophthalmology Clinic of "Sf. Spiridon" County Clinical Emergency Hospital from Iasi. We included 87 eyes, from 87 patients, distributed in 4 groups: 24 patients - the control group (cataract), 26 patients - the type II diabetes group, 16 patients – POAG group, 21 patients - the combined disease group (POAG + diabetes). We recorded data related to the age of the patients (years), best corrected visual acuity (BCVA), intraocular pressure (IOP-mmHg), perimetry parameters (MD, PSD-dB), biometric parameters (axial lengths, anterior chamber depth, CDE - Cumulative Dissipated Energy, lens thickness). The duration of glaucoma/diabetes, the type and number of glaucoma medications were noted. Similarly, the duration of diabetes mellitus, glycemic value and glycosylated hemoglobin were recorded. **Results:** Mean age calculated for the control group was 72.33+/-11.26 years, 69.04+/-9.46 years for the DM group, 75.69+/-5.54 years for the POAG group and 59.95+/-3.89 years for the combined pathology. Secondly, we found the highest IOP in the POAG+DM group, compared with the rest of the study categories (20.33+/-2.3 mmHg in group IV *vs.* 18.19+/-4.3 mmHg in group III *vs.* 15.50+/1.9 mmHg *vs.* 14.21+/-2.68 mmHg in group I), $p<0.05$. We found statistically significant differences between the four groups in respect of lens size and the CDE mean values. Our data revealed that the smallest energy was used in group IV (CDE=8.5+/-1.77), compared to all the other categories: I (CDE=17.79+/-7.36, p = 0.000), II (CDE=18.15+/-11.74, p = 0.000), III (CDE=13.90+/-8.11, p = 0.000). Estimated lens volume in group IV was 4.85+/-0.17mm in POAG+DM patients, significantly larger than the rest of the groups ($p<0.05$) **Conclusions**: younger age, higher IOP, larger lens volume and lower CDE mean values were the parameters significantly different in POAG patients, if diabetes was associated. **Keywords**: PRIMARY OPEN ANGLE GLAUCOMA, BIOMETRY, DIABETES

Glaucoma and diabetes (DM) represent one of the most frequent causes of blindness worldwide. In USA by 2020, 3.3 million patients will develop glaucoma and up to 45% of diabetic patients will develop a form of retinopathy (1). Globally, WHO

estimates a total of 360 million cases of diabetes by 2030, whereas the incidence of glaucoma will also increase. Different sources point out that in 2013 there will be about 64.3 million glaucoma patients (2), increasing to 76 million in 2020 and to 111.8 million in 2040 (3). In addition, ocular damage to diabetes is the main cause of blindness in the active population (30-69 years). Recent epidemiological studies have shown that between 1990 and 2012 there was a 27% increase in the proportion of diabetes mellitus and over 64% in diabetic retinopathy cases (4). If the diagnostic features for the primary open angle glaucoma (POAG) definition are rather clear, the pathogenesis is still incompletely elucidated.

Several risk factors involved in the development and progression of POAG have been described, but the precise contribution of each one cannot be established. The general clinical context integrates glaucomatous illness into a systemic disease category (same as diabetes), based on the principle of "a suffering eye in a suffering body" (5).

Multiple risk factors impacting over DM also influence POAG. For example, lack of exercise in aerobic conditions or obesity may influence the evolution of diabetes or IOP, hence the risk of POAG (6, 7). Theoretically, between glaucoma and diabetes, there are several common pathogenic pathways related to pressure disorders (intraocular pressure, ocular perfusion pressure), microvascular disorders and neuroinflammation. From the clinical point of view, the relationship between POAG and DM triggers 2 coordinates as following: first, presence of diabetes mellitus increases the risk of POAG development and second, in a patient with POAG, the presence of DM enhances early changes with potential neurodegenerative effect.

As such the aim of our study was to emphasize the clinical changes and biometric alterations at baseline in primary open angle glaucoma (POAG) patients, if diabetes was associated.

MATERIAL AND METHODS

The study was designed in a cross-sectional manner, between 2015-2016 in the Ophthalmology Clinic of "Sf. Spiridon" County Clinical Emergency Hospital from Iasi. We included 87 eyes, from 87 patients with indication for cataract surgery, distributed in 4 groups: 24 patients - the control group (cataract), 26 patients - the type II diabetes group, 16 patients - POAG group, 21 patients - the combined disease group (POAG +diabetes). We recorded data related to the age of the patients (years), best corrected visual acuity (BCVA), intraocular pressure (IOP-mmHg), MD (dB) and PSD (dB) in automated perimetry (24-4 program, Sita Fast, Humphrey® Visual Field Analyzer, Carl Zeiss, Meditech, CA), biometric parameters: axial lengths, anterior chamber depth, lens thickness and CDE (Cumulative Dissipated Energy) during phacoemulsification. The duration of glaucoma/diabetes, the type and number of glaucoma medications were noted. Similarly, the duration of diabetes mellitus, glycemic value and glycosylated hemoglobin were recorded.

In the study, we only included cases of uncomplicated cataract surgery. Diagnosis of POAG was based on the EGS criteria, described somewhere else (8), whereas the diagnosis of diabetes was based on patients charts and previous documents. Patients with significant general or ophthalmological disorders (e.g. age-related macular

degeneration, retinal vascular occlusions) were excluded, as well as all the cases with previous ocular surgeries.

Cataract surgery was indicated by the ophthalmologist at a time when there was significant lens opacification or when the patient requested it due to significant alterations in the quality of life and vision. Biometric parameters were recorded via immersion A-scan technique.

Ethics. All patients enrolled in the study included in the doctoral research expressed verbally and in writing an agreement for participation in the study, by signing an informed consent. The study protocol and the informed consent were approved by the Ethics Commission of the "Grigore T. Popa" University of Medicine and Pharmacy Iasi, as well as by the similar department attached to the "Sf. Spiridon" County Clinical Emergency Hospital Iasi.

Statistical analysis. Data analysis was performed using the *SPSS 20.0* software. The demographic data of the four groups were analyzed. Descriptive statistics elements were used to calculate the averages and median of all numerical parameters entered in the database (age, IOP, biometry parameters, duration of glaucoma/diabetes, number of topical medications in glaucoma, MD, PSD, CDE); $p < 0.05$ was considered statistically significant. The correlations between the variables were performed by Pearson correlation test. The correlation coefficient (r) was declared significant for a $p < 0.05$ value.

RESULTS

In the current study we evaluated data from 87 patients: 44 males (50.5%) and 43 females (49.5%). Yet the gender distribution within the study groups showed that in glaucoma patients there were more males (group III and IV), compared to healthy controls or diabetes group where females were more numerous (fig. 1).

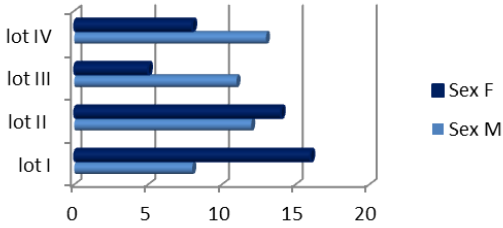

Fig. 1. Sex distribution between study groups

Mean age of the subjects was 72.33 +/- 11.26 year in the control group, 69.04+/- 9.46 years for the DM group, 75.69+/-5.54 years for the POAG group and 59.95+/- 3.89 years in the combined pathology (fig. 2). Absolute values show that the oldest patients belong to the POAG group, whereas the youngest age was calculated for the subjects with combined pathology (POAG + diabetes). Differences were statistically significant when compared DM *vs.* POAG group ($p=0.015$), Control *vs.* POAG+DM group ($p=0.000$), DM *vs.* POAG+DM group ($p=0.000$), POAG *vs.* POAG+DM group ($p=0.000$).

The IOP dynamics between the four groups followed an opposite profile compared to age distribution (fig. 2). Thus, we found the highest IOP in the POAG+DM group, compared with the rest of the study categories (20.33+/-2.3 mmHg in group IV *vs.* 18.19+/-4.3 mmHg in group III *vs.* 15.50+/-1.9 mmHg in group II *vs.* 14.21+/-2.68 mmHg in group I), $p<0.05$.

The number of substances required for IOP control in the two groups with glaucoma did not show significant differences: 3+/-0.87 *vs.* 2.85+/-1.02 drugs (POAG *vs.*

POAG+DM, p=0.489). Yet the clinical impact of this finding might be different: if diabetes was associated with POAG, the patients had significantly higher IOPs despite similar, maximal treatment.

Escalation of treatment (cataract surgery) in these glaucoma patients was necessary, at a younger age and longer life span compared to subjects with glaucoma, but without diabetes.

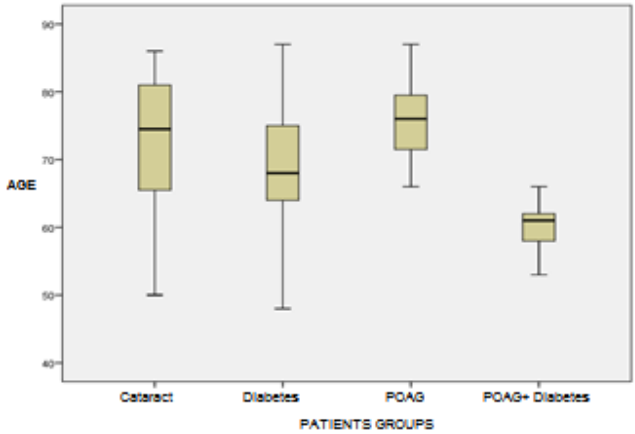

Fig. 1. Age of subjects compared between groups

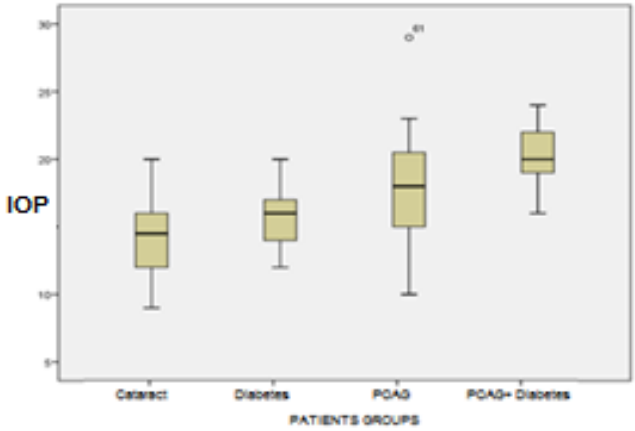

Fig. 2. IOP means compared between groups

Biometric data was summarized in Table I. There were significant differences in these parameters regarding lens size and CDE mean value. Thus, the smallest amount of ultrasound energy was necessary in the POAG+DM group, when compared to the other study group categories. Differences in CDE values for the compared groups were: I *vs.* IV (p=0.000), II *vs.* IV (p=0.000), III *vs.* IV (p=0.000). Also, the largest lens was found in group IV, if diabetes was present in glaucoma patients (p<0.05 compared to healthy controls or POAG patients). No differences were present between the four groups regarding axial lengths (mm) or ACD (mm).

TABLE I

Comparison of means in biometric data between study groups.

Parameter	Control group	Diabetes mellitus group	POAG group	POAG+DM group
AL (mm)	22.87+/-0.64	22.97+/-0.40	22.74+/-0.66	22.87+/-0.65
ACD (mm)	2.96+/-0.41	2.81+/-0.31	2.80+/-0.54	2.74+/0.31
L (mm)	2.36+/-0.35	4.12+/-0.26	3.79+/-0.63	4.85+/-0.17
CDE (mm)	17.79+/-7.36	18.15+/-11.74	13.90+/-8.11	8.5+/-1.77

AL – axial lengths; ACD - anterior chamber depth, L – lens, CDE – Cumulative Dissipated Energy

Clinical implication of this result proves that the structure of the lens in the glaucoma patients is different if diabetes is present; moreover, cataract surgery becomes necessary in younger ages and dictated also by a significantly higher IOP under maximally topical tolerated medication and increased lens size.

From functional deficit point of view, in this study the MD values were similar between groups and helped us categorize our glaucoma patients as having an "advanced disease", according to the EGS criteria (tab. II). However, it should also be considered that the MD recordings might have been influenced by the degree of lens opacification (cataract), mostly since there was no concordance with the degree of localized glaucoma damage (PSD).

Separate analysis of PSD in our glaucoma patients showed that in the combined pathology (POAG+DM) group, the localized deficit was less prominent in comparison with the POAG group. Age has been shown to be a risk factor in POAG, therefore the significantly younger age of the POAG+DM group compared to POAG group might be an actual explanation for this finding. Duration of glaucoma between groups III and IV was similar (45.63 +/- 26.48 months *vs.* 36.86+/- 15.86 months, p>0.05).

TABLE II

Functional perimetric parameters compared between glaucoma groups in the study

Group	POAG group	POAG+DM group	p<0.05
MD (dB)	-13.59+/-9.35	-12.13+/-8.9	p=0.683
PSD (dB)	4.25+/-4.22	2.05+/-0.90	p=0.026

From the metabolic point of view, both groups of diabetic patients exhibited similar values of the blood sugar level: 171 mg/dL in group II *vs.* 155.05 mg/dL in group IV, p> 0.05. Yet a significant longer duration of diabetes was found in group II compared to group IV (133 +/- 77.82 *vs*. 115 +/- 81.24 months, p = 0.004), combined also with a poorer long term metabolic control. HbA1c mean values (%): 8.12 +/- 1.81 (group II) *vs.* 7.12 +/- 1.35 (group IV), p = 0.036.

In POAG and diabetes patients, clinical correlations relevant for this study were depicted in Table III.

PSD is correlated negatively with the age, therefore an earlier glaucoma deficit in younger patients, if diabetes is also present in POAG patients. An increase in medication was correlated with a decrease of the MD levels, stating that we treated more aggressively the patients once we observed a decrease in the functional perimetric parameters

levels. No correlation was detected between the perimetric indices, as they might have not necessarily reflected the reality in terms of glaucoma severity, but lens opacification degree (MD is influenced by the opacities in the lens, as opposed to PSD).

Mean IOP is correlated with the intensity of treatment (number of topical medications) and the blood sugar level. Therefore, if diabetes is associated with POAG, it induces an increase in IOP, increasing the demand for an aggressive treatment.

In POAG, clinical correlations relevant for this study were depicted in Table IV.

TABLE III

Correlations between clinical parameters in POAG+DM patients

Pearson test (r) p<0.05	Age	IOP	Number of medications	MD	PSD	Blood sugar	HbA1c
Age	1	-0.148 0.521	0.09 0.681	0.322 0.207	-0.461 0.039	-0.195 0.396	-0.112 0.630
IOP	-0.148 0.521	1	0.529 0.14	0.307 0.231	0.287 0.208	0.520 0.016	0.140 0.546
Number of medications	0.95 0.681	0.529 0.014	1	-0.545 0.024	-0.021 0.929	0.135 0.561	0.428 0.053

TABLE IV

Correlations between clinical parameters in POAG patients

Pearson test (r) p<0.05	Age	IOP	Number of medications	MD	PSD	Blood sugar
Age	1	0.154 0.569	0.338 0.889	-0.533 0.091	-0.01 0.970	-0.133 0.624
IOP	0.154 0.569	1	0.790 0.042	0.083 0.807	0.513 0.042	0.543 0.030
Number of medications	0.038 0.889	0.790 0.042	1	0.503 0.115	0.311 0.024	0.521 0.039
MD	-0.533 0.091	0.083 0.807	0.503 0.115	1	-0.649 0.031	0.427 0.191
PSD	-0.01 0.970	0.513 0.042	0.311 0.024	-0.649 0.031	1	-0.447 0.082
Blood sugar	-0.133 0.624	0.543 0.030	0.521 0.039	0.427 0.191	-0.447 0.082	1

IOP levels in these patients correlates positively with the functional localized deficit (PSD) and with the increase of blood sugar levels (although we were not analyzing patients with diabetes). Of course, the higher the IOP became in these

patients, the more aggressive the treatment became. In this study category, we obtained a correlation between the perimetric indices (MD/ PSD) which might indirectly state that based on older age and lack of a metabolic disorder such as diabetes, the MD was less influenced by the lens compound contributing to the general reduced retinal sensitivity (cataract formation) and the glaucoma disease evolved in its specific correlated pattern.

DISCUSSION

In this study, the presence of diabetes modified the clinical and functional parameters, all together with some phacoemulsification parameters (CDE) in glaucoma patients. Biometric measurements were similar between groups, except for the mean lens thickness (mm) that was increased in the combined pathology group, compared to the other categories of interest (controls or glaucoma patients). This only proves that the presence of diabetes induces an early and excessive hydration of the collagen lamellas, based on some very low levels of sorbitol in adult diabetic lenses. The altered osmotic mechanism increases the risk of cataract even more, altogether with glycation and oxidative stress (11). The relationship between the polyol pathway and sugar cataracts has been studied extensively using streptozotocin-induced diabetic rats and galactose fed rats as animal models for insulin-dependent diabetes mellitus (IDDM). In these models, sugar cataracts progress (12).

Our study proves that the metabolic disorders are more frequent in younger female patients, while in older male patients' glaucoma is more frequent. A higher mean IOP at presentation, combined with younger age and increased lens volume required prompt cataract surgery intervention in the combined group. Aim of our approach was to decrease IOP and reduce the number of topical medications, therefore an improvement quality of life in our POAG patients. It is true that in both glaucoma groups, the number of topical substances was maximal and comparable, yet the mean IOP was significantly higher in the POAG+diabetes group. Therefore, a supplementary metabolic disorder may alter the overall status in glaucoma patients.

An IOP in its high teens (18 mmHg, as we calculated in our study) in a moderate-advanced glaucoma patient increases the risk of POAG progression; therefore, a surgical intervention was discussed. In the context of glaucoma patients, cataract extraction decreases IOP and/or lowers the number of substances used to control IOP (13). Moreover, cataract extraction before trabeculectomy offers a safer approach both for the patient and the surgeon if performed first (13). As such we preferred this approach in our study. Adding a fourth substance would have been an option if the stage of the glaucoma was different (early) and if the quality of life in our patients had remained the same.

Using the lowest ultrasound energy in the combined pathology group pleads only for the above-mentioned changes induced by metabolic imbalances in the lens, if diabetes is discussed. Therefore, a different structure and density is met in the diabetic lens compared to the normal involutional changes induced by age alone. The lens capsule is impermeable, therefore an increase in the oncotic pressure within the lens accelerates cataract formation. Intense hydration of collagen lamellas produces soft intumescence of the lens in diabetic cataract compared to sclerotic changes in

age related cataract.

Functional parameters in glaucoma patients are also influenced by diabetes. Based on the Hodapp classification, our POAG cases are categorized as moderate to advanced disease, but formation of cataract can artificially decrease MD values and influence glaucoma severity scale. In this respect, by inspecting the PSD maps the clinician might interpret the parameters in a different way as it was the case in our study. The discrepancy between the MD/PSD maps pleaded also for a cataract influence over the parameters than only glaucoma damage. An interesting aspect that we found in our study was that the mean PSD values in the combined pathology (POAG+diabetes) group were decreased compared to the POAG group. A possible explanation for less localized damage in POAG+diabetes category could be the age aspect: age glaucoma damage increases with age; therefore, an older age might have more pronounced damage (POAG group, mean age=75 years old) compared to younger age (POAG+diabetes group, mean age = 59 years-old). Still it is difficult to establish the exact glaucoma extension of damage in both groups, since patients from both categories were evaluated before cataract surgery, for which there was a strong recommendation.

Study limitations were the small number of patients and the echo-biometric methods for the anterior segment measurements.

CONCLUSIONS

In our study we found several clinical changes that "modulated" the decision about the best treatment options in primary open angle glaucoma patients, especially if they associated a general risk factor such as diabetes. Further studies and more data, especially using recent advances in ocular imaging such as AS-OCT technology, are needed to provide a complete overview of anterior segment measurements, so as the best management is offered to diabetic glaucomatous patients.

NEWS

THE BENEFITS OF SODIUM-GLUCOSE COTRANSPORTER 2 INHIBITORS ON METABOLIC PARAMETERS

Sodium-glucose cotransporter 2 inhibitor (SGLT2i) blocks reabsorption of glucose by inhibiting SGLT2 in kidney, promotes the renal excretion of glucose and improves blood glucose control without requiring insulin secretion. A recent study retrospectively picked up patients with type 2 diabetes who had been continuously prescribed SGLT2i for 3 months or more (26 patients treated with tofogliflozin, 34 patients with canagliflozin, 27 patients with empagliflozin, 23 patients with ipragliflozin, 68 patients with dapagliflozin and 71 patients with luseogliflozin) and compared metabolic parameters including coronary risk factors before the SGLT2i treatment with the data at 3 and 6 months after the SGLT2i treatment started. Each SGLT2i ameliorated metabolic parameters, in different patterns. SGLT2is reduced body weight, systolic and diastolic blood pressures, plasma glucose, hemoglobin A1c, aspartate aminotransferase, alanine aminotransferase, γ-glutamyltransferase, uric acid, triglyceride and non-high-density lipoprotein-cholesterol (HDL-C), and elevated HDL-C; however, they did not affect LDL cholesterol levels. Change in each metabolic parameter was significantly correlated with each metabolic parameter at baseline (Yanai H, Hakoshima M, Adachi H, Kawaguchi A, Waragai Y, Harigae T, Masui Y, Kakuta K, Hamasaki H, Katsuyama H, Kaga T, Sako A, Effects of Six Kinds of Sodium-Glucose Cotransporter 2 Inhibitors on Metabolic Parameters, and Summarized Effect and Its Correlations with Baseline Data. *J Clin Med Res* 2017; 9(7): 605-612. doi: 10.14740/jocmr3046w. Epub 2017 May 22).

PARTICULAR ASPECTS IN A WILLIAMS - BEUREN SYNDROME CASE OF A 15-YEARS- OLD TEENAGER (Abstract): Williams-Beuren Syndrome is a rare genetic disease determined by a submicroscopic deletion located on the long arm of chromosome 7. This disease was first described by Doctor J.C.P. Williams in 1961 and was later updated by Beuren. This disease occurs at a ratio of between 1/20,000 and 1/7,500. It is a congenital disease, affecting all ethnic groups and all populations world-wide, independent of sex. In most cases, those affected, are considered isolated occurrences especially because the parents of these patients are clinically healthy. In rare cases, this disease can be inherited from one parent, meaning, the inheritance pattern is autosomal dominant. Parents cannot benefit from prenatal diagnostic testing except in the case in which another family member has already been diagnosed with this disease. The only diagnostic test for this syndrome is through FISH which can stipulate the deleted DNA segment on the 7 q 11.23 chromosome. **Keywords**: WILLIAMS-BEUREN SYNDROME, KARYOTYPE, FISH TECHNIQUE, AORTIC STENOSIS.

The parents asked for genetic testing to be done since their daughter was suspected for having Williams-Beuren Syndrome. The general clinical examination showed: fragile phenotype, pale skin, light hyperelasticity, cephalic extremity: bilateral epicanthus, retraction of the maxillary floor, short, flat nose, symmetric and hypertrophic nasal alae, stellar iris, macrostomy and micro retrognathia (fig. 1). The skeletal system: pectus carinatum, kyphotic posture, narrow thorax, fallen shoulders (fig. 2), bilateral pes plantus, bilateral femoral ante version, long fingers and toes. Cardiovascular system: hypoplasia of the abdominal aorta and the presence of mitral valve prolapse. Digestive system: irritable bowel syndrome, constipation, nonseptic chronic colitis. Normal urinary system. Genital system: echographic vascular uterine dila-

tations. Endocrine system: hypocalcemic spasmophilia, hypothyroidism. Nervous system: OTR present and hyper-sensitive, sociable, friendly, difficulty in learning and concentration; IQ=56. Paraclinical investigations: normal complete blood count and normal renal and hepatic functions. Hypercholesterolemia and low ionic calcium are also present.

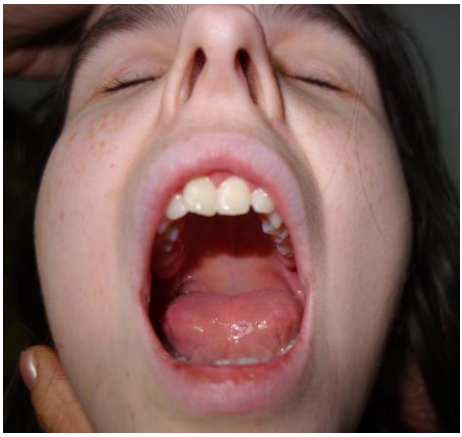

Fig.1. Macrostomy with full lips, macroglossia

Fig. 2. Kyphotic and scoliosis posture fallen shoulders

Genetic exam: The patient is the second child of three children. The couple is not of consanguineous origin. The pregnancy progressed abnormally with episodes of imminent abortion, treated at the moment of occurrence. The baby was born naturally at full term with a cranial presentation. The baby's weight: 2,950 grams. APGAR 8. The baby was breastfed. According to the mother's declaration, the baby's psychomotor development was normal. In 2003, the patient was admitted to the Pediatric Hospital in Iasi, where she underwent a clinical examination, resulting in the presumption of Williams Syndrome. A microculture from a peripheric blood sample yielded a karyotype through PHA stimulation with and without G markings with a chromosomic formula of 46, XX, which is normal. In 2014, the MEDSANA genetics laboratory in Bucharest used a MLPA (Multiplex ligation-dependent probe amplification) technique and the karyotype had deleted DNA sequences in the 7 q 11.23 region which were deleted hemizygous DNA sequences specific for patients diagnosed with Williams Syndrome. Thus, in the present case, the patient has been positively diagnosed with Williams-Beuren Syndrome. The patient's siblings of 17 and 15 years of age, respectively, have a longiline phenotype, proportional body structure, normal age-oriented intellectual development, renal abnormality, hernia, deglutition difficulty and hypercalcemia.

Diagnostic: Williams-Beuren Syndrome, hypoplasia of the abdominal aorta, hypothyroidism, spasmophilia with hypocalcemia and normal magnesium values.

DISCUSSION

The clinical diagnosis of Williams-Beuren Syndrome can only be obtained

through team work between geneticists, cardiologists, pediatrists, ophthalmologists, otorhinolaringologists, neurologists, psychologists and other specialists. The diagnosis can only be confirmed by studying the karyotype through the MLPA technique of the critical zone on 7 q 11.23 where the genes are located (ELN-LINK1) (2). Common signs of the syndrome are: specific facial features, vascular abnormalities of the heart (3), hypercalcemia, low birth weight, stunted growth, low muscle tone, deglutition difficulty, irritability, colics in the first year of life, abnormal dentition, abnormal kidneys, hernia, hyperacusis (4), friendly character with an interest in adults (5), stunted development, problems with concentration, intellectual handicap of varying degrees, underdeveloped fine motor skills, they are bothered by loud sounds such as clapping, loud laughs, other loud sounds, dogs barking (6). The patient in this case showed 14 out of the 20 possible signs of those missing are: normal birth weight, stunted growth in the first years of life, abnormal kidneys, hernia, difficulty in deglutition and hypercalcemia (1).

Treatment and follow-up

Currently, there is no specific treatment. The only treatment available is symptomatic. Calcium and vitamin D supplements are not administered. It is important that the patient refrains from sun exposure. Logopedic therapy is necessary for language rehabilitation, vocabulary improvement, receptive and expressive language development. Behavioral therapy is the basis for learning for these children, which can take years, based on the child's learning capacity. Kinesiotherapy is also an important aspect. Cardiovascular monitoring is necessary to track renal and aortic stenosis's that can form. The blood pressure of the patient should be monitored in both arms. Psychotropic drugs are necessary in treating attention deficit. Periodic endocrine check-ups are needed to diagnose type 2 diabetes and hypothyroidism in the early stages (7). Ophthalmic, hearing, urinary and genital assessments are performed. Calcemia, calciuria and cholesterol levels are also monitored. Psychologic evaluations and psychiatric treatments are necessary to monitor cognitive deficiencies and behavior (8).

Evolution and Prognosis: Facial signs become more prominent with time. Vascular stenosis varies in several degrees of severity. Reactions to stimuli are accentuated. The patient may suffer from spatial-visual and coordination problems. They do not have true spatial perception, suffering from a fear of heights and uneven surfaces. Moreover, they are socially adapted. However, they will need constant adult supervision for their entire lives, only able to perform easy tasks.

Genetic advice: Prenatal diagnosis, through echography or other tests, is not possible. The only investigations permitted is an invasive technique through chorionic villus sampling and using the FISH (Fluorence In Situ Hybridization) technique thereafter in the 12th week of gestation; also, amniocentesis can be performed in weeks 16-18 (9). There are currently no methods of prevention. The recurrence risk in the future children of parents with this syndrome is less than 5%. The recurrence risk of the patient's siblings of having this syndrome is less than 1%. The recurrence risk that the patient will have children with this disease is 50%.

CONCLUSIONS

In our vision, we found the particularities of this case: cardiovascular abnormali-

ties such as abdominal aortic hyperplasia, the absence of hypercalcemia and present of hyper-cholesterolaemia. Caring for a child with Williams Syndrome can be difficult and could benefit from familial support. All family members should try to maintain a friendly behavior, a calm demeanor and understanding. The family will need to work in close contact with the child's family doctor as well as other specialists to maintain a certain degree of normality in every stage of the child's life.

LIMITATION OF THE FETAL ULTRASOUND IN DETERMINING THE FETAL GENDER

V. G. Rugină[1], D. Mihalcea[1], Aniela Rugină[1*], Letiția Doina Duceac[3], I. Sârbu[2], Iulia Ciongradi[2], A. Cărăuleanu[1]

LIMITATION OF THE FETAL ULTRASOUND IN DETERMINING THE FETAL GENDER (Abstract): Genital abnormalities are a rare finding on prenatal ultrasound but can be seen when detailed examination is performed following detection of another structural abnormality or, and more commonly, when the genitalia are examined because of parental curiosity. The etiology of these unexpected genital anomalies is broad and includes an isolated anomaly, an underlying genetic syndrome, Intra-Uterine Fetal Growth Restriction (IUGFR), chromosomal abnormalities and, although rare, anomalies of steroid biosynthesis or androgen insensitivity. We report the case of a 31-years-old patient that followed the prenatal consultation and the fetus was diagnosed after being born with a rare severe case of perineal hypospadias. **Keywords**: HYPOSPADIAS, INTERSEXUALLITY DISORDER, ULTRASOUND.

Ultrasound is principal method in most parts of the world for prenatal sex determination. Indication for prenatal sex determination can be medical or nonmedical. The medical indication is: X-linked disorders, testicular feminization syndrome, pseudohermaphroditism, genital anomalies, ambiguous genitalia, and determination of zygosity in multiple pregnancy (1, 2, 3, 4, 5). The nonmedical reasons are: preparturition shopping, curiosity, husband/relatives' request (4).

CASE REPORT

We report the case of a pregnant woman aged 31-years-old, routinely ultrasound examined initially at 6 weeks of gestation, when a unique embryo with no abnormal findings was identified.

All ultrasound examinations were performed transabdominally using a Voluson E8 Expert machine (BT10 software) with a 4e8-MHz curved array three-dimensional transducer.

Subsequent examinations revealed the diagnosis of Trombophilia at 10 weeks of gestation treated with Enoxaparinum 4,000 UI anti-XA and Gestational diabetes mellitus type A1 treated by diet modification.

Subsequent examinations at 18, 22, 28 weeks of gestation revealed a normal morphological female fetus (fig. 1, 2).

At 32 weeks of gestation, during the

third trimester morphology, the ultrasonic aspect of the gender modified- instead of labia we saw scrotal folds, which include both testes and no penis (fig. 2). The fetal biometric measurements correlated with his estimated gestational age showed no fetal anatomic abnormality except in the external genitalia.

Both parents were informed of the development and to establish a diagnosis they were advised for a diagnostic amniocentesis or a noninvasive blood test from maternal serum to determine the fetal gender. They refused.

Fig. 1. Ultrasound showing attempts of viewing female genitalia (22 weeks)

Fig. 2. Ultrasound showing female genitalia (22 weeks)

Fig. 3. Ultrasound showing male genitalia (32 weeks)

After 39 weeks of gestation, a baby presenting a severe birth defect of the external genitalia was born through C-section for the diagnosis of acute fetal distress.

The aspect of external genitalia was ambiguous, with two separated, non-fused labioscrotal folds, a relatively well represented and differentiated phallus in the midline, covered by excessive skin on the dorsal aspect; a single orifice, the urethral meatus was opening below the phallus, in the perineum skin (fig. 4). At palpation, gonads were present in each of the labioscrotal folds and rectal examination did not revealed any abnormal structures. Because of the findings at birth, the diagnostic

in this case is severe perineal hypospadias with incomplete penoscrotal transposition; male sex was also confirmed genetically, the karyotype being a normal 46 XY; no associated malformations of urinary tract were identified. The boy was scheduled for hypospadias repair.

Fig. 3. Severe perineal hypospadias with incomplete penoscrotal transposition

DISCUSSION

We present a case of severe hypospadias where the prenatal ultrasound allowed us to ascertain its severity and the perineal anatomical relationships, to advise parents on the expected surgical outcomes.

Hypospadias is one of the most common congenital anomalies, with an estimated prevalence between 0.2 and 4.1 per 1,000 live births of both sexes (6). It is defined by a failed development of the spongy urethra and ventral foreskin (7). The incomplete fusion of the urethral folds' results in anomalous location of the meatus at some point of the ventral side of the penis, instead of the tip. The foreskin does not fuse on the ventral side, because of nonunion of ectodermal folds, being redundant dorsally. It is often associated with a ventral curvature of the penis (also known as chordae), caused by atresia of the corpus spongiosum distal to the hypospadias urethral meatus.

The severity of hypospadias is graded upon the position of the urinary meatus and the extent of ventral penile angulation. Severity rises as the distance of the displaced urethral opening increases from the normal position at the tip of the glans and with increasing penile curvature. Hypospadias is classified into three grades, depending on the location of the meatus: first degree/mild (glandular or coronal urethral opening), second degree/moderate (in the penile shaft) and third-degree/severe (urethral opening within the scrotum or perineum).

The exact etiology of the disorder remains unknown. It seems that the origin of hypospadias is multifactorial; several risk factors have been identified such as genetic predisposition, placental insufficiency, and substances that interfere with natural hormones, endocrine disruptors (7, 8, 9, 10).

Hypospadias usually is not a single anomaly, up to 40% of fetuses have associated upper urinary tract anomalies. Cryptorchidism and inguinal hernias are found in 7-10% of all hypospadias cases and are considered the most common extragenital anomalies (11).

Other extragenital malformations (5-10%) are heart defects, cleft palate, neural tube defects, and anorectal malformations. It has also been described in the context of various genetic syndromes, such as XXY, XXXXY, trisomies 13 and 18, Fraser syndrome, the Smith-Lemli-Opitz, Opitz-Frias Wolf-Hirschhorn (9).

Attention should be paid in detecting abnormalities in the external genitalia dur-

ing second trimester ultrasound. Conventional sonographic criteria for the diagnosis of hypospadias are a small penis, with a blunted bulbous tip and two parallel echogenic lines at the top, representing the lateral folds of the foreskin. This was called by Meizner (12) the "tulip sign" for the diagnosis of severe hypospadias. This sign could not be seen in our case (fig. 3).

However, in certain cases, especially when the testicles are undescended, it is difficult to distinguish between external female genitalia and severe hypospadias. So, ambiguous genitalia would be included as main differential diagnosis, congenital adrenal hyperplasia as primary cause. The sonographic findings in this case are: clitoromegaly, which can mimic a penis, and enlarged adrenal glands bilaterally with discoid morphology (13). This diagnosis can be ruled out by obtaining male karyotype, but in this cases the parents refused both attempts in doing so.

Although 2D ultrasound is still the gold standard for diagnosing fetal genital abnormalities, prenatal diagnosis using 3D has been reported previously (14, 15).

By 3D representation, the external genitalia are shown with a great clarity of structures and their anatomical relation which confirm the diagnosis of third-degree hypospadias. In this case, even though severe hypospadias was supposed, the position of the fetus and the quantity of amniotic fluid were not favorable for 3D imaging when it was available (fig. 1). In conclusion, the diagnosis is not supported by 3D imaging, therefore, the multiplanar representation of the genital area that would allow us to obtain a better understanding of hypospadias and get proper parental counseling from pediatric surgeons, with the possibility to report the prognosis and future treatment was not available until birth.

CONCLUSIONS

If in most cases, normal 2D ultrasound along with 3D imaging is more than enough in establishing fetal gender, we conclude that in selected cases fetal karyotype obtained by amniocentesis is needed to make a positive diagnosis of gender and distinguish between a single anatomical perineal malformation and a genetic syndrome.

Also, we argue that 3D imaging when possible is an important tool in assessing the severity and the prognosis of the congenital perineal malformation.

MITOGEN-ACTIVATED PROTEIN KINASE SIGNALING PATHWAY IN CUTANEOUS MELANOMA: AN UPDATED REVIEW

The molecular pathogenesis of cutaneous melanoma is strongly correlated with a constitutive activation of the mitogen-activated protein kinase (MAPK) signaling pathway. The most frequently affected genes are v-raf murine sarcoma viral oncogene homolog B (BRAF) and neuroblastoma Ras viral oncogene homolog (NRAS), which show mutations in up to 40% to 50% and 15% to 20% of melanomas, respectively. The development of targeted therapy for metastatic melanomas that harbor a specific subset of BRAF mutations has led to the combined approval of 3 drugs (vemurafenib, dabrafenib, and trametinib) and their companion diagnostic molecular tests. These tests are real-time polymerase chain reaction–based assays designed to detect missense mutations at nucleotide position 1799 of BRAF, which result in the substitution of valine at amino acid position 600 of the BRAF protein (BRAF V600 mutations). Recently, the widespread availability of gene sequencing has led to the identification of multiple additional BRAF mutations of uncertain pathogenic and therapeutic significance. Also, gene sequencing has revealed that melanomas can have mutations in many other genes of the MAPK signaling pathway, some of which might be clinically relevant. In this paper, the authors provide a general overview of the role of the MAPK pathway in the pathogenesis of cutaneous melanoma, focusing on BRAF mutations and their therapeutic implications (Acosta AM and Kadkol SS. Mitogen-Activated Protein Kinase Signaling Pathway in Cutaneous Melanoma: An Updated Review. *Archives of Pathology & Laboratory Medicine* 2016; 140(11): 1290-1296).

COMPLEMENTARY MULTIDISCIPLINARY ELDER ABUSE SERVICE IN a GERIATRIC CLINIC (Abstract) **Aim:** To describe a pilot, innovative intervention project combining the adoption and adaptation for hospital use of a screening instrument designed for use in primary health care settings in Canada (and translated into 6 other languages) and a dialogical narrative therapeutic approach. The development of a complementary multidisciplinary elder abuse service (CMEAS) in a private-public partnership. **Material and methods:** Between June 2015 – March 2016 elderly hospitalized in Iasi town, Geriatric Clinic and suspected of being abused had the benefit of a complementary multidisciplinary elder abuse service (CMEAS) after being screened for abuse, neglect or abandonment experiences. **Results:** A total of 450 patients admitted to the Geriatric Clinic were invited for the study and 152 raised suspicion of abuse experiences and were screened with EASI. Of these patients, 132 where found positive and were invited to participate in CMEAS. **Conclusions:** Such a multidisciplinary service requires the collaboration between the geriatric team (medical service), psychologist, social worker, legal advisor, and psychiatrist, referral of cases to relevant public and private community services and their monitoring after hospital discharge throughout project duration. **Keywords**: COMPLEMENTARY SERVICES, MULTIDISCIPLINARY APPROACH, ABUSE, ELDERLY.

„Elder abuse is a global public health and human rights problem that crosses sociodemographic and socioeconomic strata" (1). The presence of abuse in geriatric care complicates health care exponentially. Elder abuse is associated with a long series of health problems, a high level of emergency service utilization, including readmissions within less than one month, and financial burden for the family and community public services (1).

Healthcare practitioners play a key role in the identification of elder abuse, quite often medical checkups being the only regular interaction that older people have outside their home. Nowadays, elder abuse is encountered routinely in medical practice (2).

In Romania, elder abuse has not been systematically identified in public hospital or primary medicine settings. Elder abuse very recently became a health policy topic as the Romanian government adopted in

July 2015*" The National Strategy for the Promotion of Active Aging and the Protection of Elderly 2015-2020".* The pilot experimentation of a CMEAS in an Iasi geriatric clinic was done in the context of the lack of psychological, social, legal and psychiatric services in the public hospital and the lack of referral of potentially identifiable cases to the relevant existing community services.

In this descriptive study of the CMEAS a public-private partnership was created between a geriatric clinic, two universities, and four professional associations (psychologists, family practitioners, nurses, and social workers). The partnership was funded via NGO Fund in Romania, under the project „I Refuse Silent Abuse", initiated by the Psiterra Association based in Iasi.

MATERIAL AND METHODS

The medico-psycho-social-legal model used for the identification of abuse in the hospitalized elderly relies on hospital-based medical geriatric care and MCEAS and referral and monitoring after discharge in the community. This model was developed in a 13-month project and was implemented during the last 10 months of the project at a geriatric clinic. It had the following stages: 1) geriatric assessment; 2) obtaining informed consent; 3) use of Elderly Abuse Suspicion Index (EASI) as a screening instrument; 4) initial psychological assessment; 5) social inquiry report; 6) CMEAS team meeting with the patient - using both dialogical and narrative principles; 7) implementation of the personalized intervention plan; 8) patient's discharge from hospital, monitoring, and the case closure.

A total of 450 patients admitted to the Geriatric Clinic were invited for the study and 152 raised suspicion of abuse experiences and were screened with EASI. Of these patients, 132 where found positive and were invited to participate in CMEAS.

The assessment interview was in fact a narrative conversation (6) facilitated by a psychologist previously trained in narrative therapy by courses accredited by the *Romanian College of Psychologists* organized by Psiterra Association in Iaşi, Romania.

If abuse was suspected but the patient was denying it or was reluctant to disclose information, the psychologist left his/her contact information, the description of the CMEAS and of the project, letting the patient know that he/she could contact the team any time he/she is ready or becomes preoccupied with the abuse and its effects. If the patient accepted the CMEAS, or CMEAS and referrals, the social worker initiated the social inquiry. At this first meeting the psychologist's goal was to get patient's agreement for an open dialogue meeting (with the doctor, psychologist and social worker, at least) (7).

The information collected in this study was evaluated using clinical and epidemiological methods, statistical and mathematical techniques and procedures, descriptive statistics were performed using software *SPSS 18.0.*

RESULTS

During the 10 months of CMEAS implementation of the Psiterra narrative and dialogical model of care 152 elderly patients of the total of 450 eligible admitted elders were screened using EASI. They were all referred to CMEAS and following psychological assessment the presence of abuse was substantiated in 132 (29.3%) of the referred patients.

Working narratively and offering the patient the opportunity to decide on any aspect of the intervention plan, a total of 61 patients (46.2%) accepted to receive com-

plementary services during hospital stay and accepted to be referred to community public and private services, including the services offered by the religious organizations (parishes they belonged to). Other 41 patients (31.1%) accepted only CMEAS services during their hospital stay, but no referrals. That is, a total of 102 elderly patients with confirmed suspicion of abuse received services during their hospitalization. Only 30 elderly (22.7%) identified with abuse refused to receive services either from CMEAS or to be referred to existing community services.

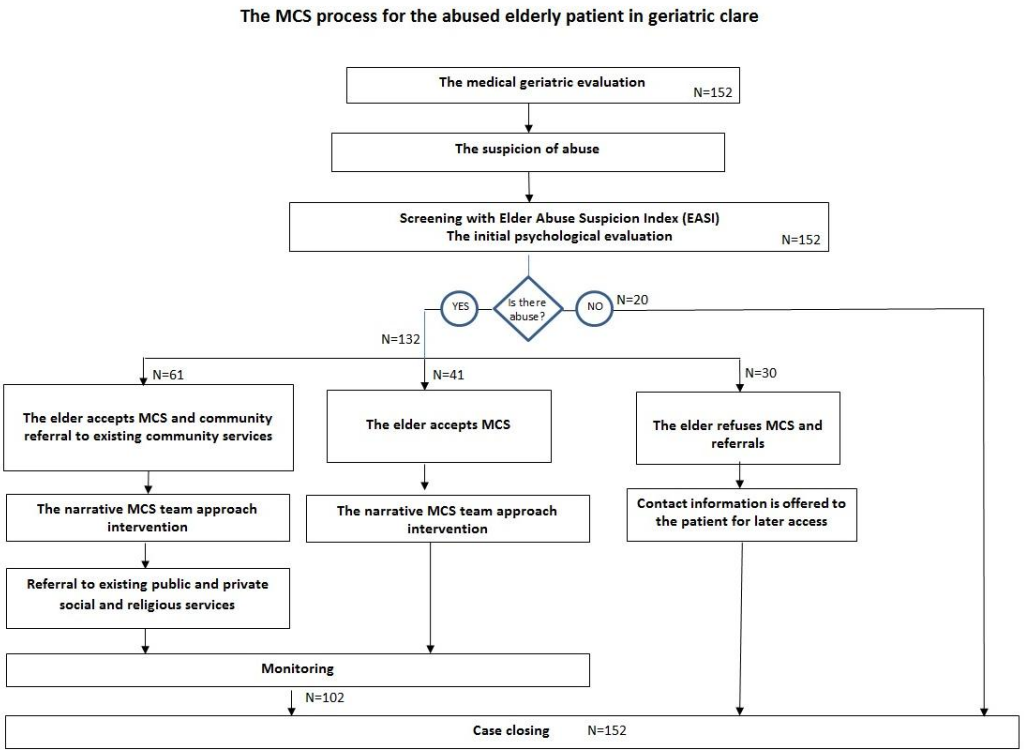

Fig. 1. MCS process diagram

DISCUSSION

The demonstration project for the implementation of CMEAS based on dialogical and narrative principles proved influential on three levels:

1) clinical (micro), improving the well-being of the elderly patient (both during hospital stay and after discharge, the patients being monitored until the end of the project);

2) organizational (mezzo), by providing complementary services only to the geriatric ones, through training seminars on the screening methods for elder abuse using the EASI scale, training seminars accredited by CMR on recognizing elder abuse and hospital-based multidisciplinary intervention;

3) by integrating medical, psychological and social services and promoting the awareness of elder abuse; and sectorial (macro) by the promotion of public awareness about elder abuse and by launching a

dissemination campaign in professional media and to major public stakeholders in healthcare and psycho-social care in Romania.

As to professional training and development, as other reports suggest (3), the healthcare professionals are in an ideal position to identify, support and refer the persons who experience abuse while aging. The lack of specialized training to deal adequately with cases of suspected abuse can be a possible explanation for the fact that many cases of elder abuse go unreported.

The innovative intervention piloted the development of multidisciplinary complementary services in a public hospital in line with the new strategic directions within *"The National Health Strategy and for the Promotion of Active Aging" (*2015-2020). In the complex situation of geriatric patients exposed to abuse, neglect or abandonment it is even more relevant to read Rita Charon (Columbia University, New York) saying that *„We are all united in the efforts to treat patients, no matter of our specific skills and responsibilities. We together have the capacity to confer dignity on the lives of the sick, and, one may argue, we require that all of us join in the commitment to dignified care"* (8).

Making central the voice of the abused elderly and giving priority to his/her voice permits „the facilitation of the freedom to choose among alternative behaviors, all the areas of functionality of the assisted person, contributes to his or her development, to his or her plenary experience of freedom and of meaningfulness. This axiological experience is inducing a modification of what we may describe as internal motivation and a reorientation in relation to change, initially having an ambivalent position towards change" (9).

Identifying the traumatic experiences that affect compliance and patient adaptation is crucial in the case of elderly patients; the rapid identification of abuse has also an effect on changing the perception of health care personnel regarding the quality of health care provided to the patients (10).

CONCLUSIONS

In our study, of the 450 patients admitted to the geriatric clinic during the 10-monthscreening, one third (33.3%) were identified as having been exposed to various types of abuse, neglect or abandonment and were referred to CMEAS by the medical staff. The 20 false positive responses (13% of the total 152 patients screened for abuse with EASI) underscore the importance of professional training in the use of screening instruments as well as the need for immediate referral to psychological and social services able to substantiate abuse experience and to support the access to existing resources in the family and community.

Our study underscores the high sensitivity of the assisted elderly in the communication with the medical staff, increased trust in participating in medical care activities, improvement of symptoms, and a shorter hospital stay; on the medical staff side, there was a greater sensitization towards the elder patient's needs and a more open personal expression in relation to the patient.

NEWS

CARDIOVASCULAR SAFETY OF CELECOXIB, NAPROXEN, OR IBUPROFEN FOR ARTHRITIS

In the PRECISION trial (Prospective Randomized Evaluation of Celecoxib Integrated Safety versus Ibuprofen or Naproxen) the goal was to asses cardiovascular, gastrointestinal, renal, and other outcomes with celecoxib compared with two nonselective nonsteroidal antiinflamatory drugs (naproxen or ibuprofen). Patients who required NSAIDs were randomly assigned to receive celecoxib (100 mg twice a day), ibuprofen (600 mg three times a day), or naproxen (375 mg twice a day). For patients with rheumatoid arthritis investigators could increase the dose of celecoxib (200 mg twice a day), the dose of ibuprofen (800 mg three times a day) or the dose of naproxen (500 mg twice a day). Also for patients with osteoarthritis, increases of the doses of naproxen or ibuprofen were permitted. A total of 24,081 patients were assigned to the celecoxib group, the naproxen group, or the ibuprofen group for a mean treatment duration of 20.3±16.0 months and a mean follow-up period of 34±13.4 months. 68.8% of the patients stopped taking the study drug, and 27.4% discontinued follow-up. The results showed that the risk of gastrointestinal events was significantly lower with celecoxib than with naproxen or ibuprofen. Also the risk of renal events was significantly lower with celecoxib than with ibuprofen but was not significantly lower with celecoxib than with naproxen. The study concluded that at moderate doses, celecoxib was noninferior to ibuprofen or naproxen with regard to the primary composite outcome of cardiovascular death, nonfatal myocardial infarction, or nonfatal stroke (Nissen S, Yeomans N, Soloman D et al. Cardiovascular Safety of Celecoxib, Naproxen, or Ibuprofen for Arthritis. *New England Journal of Medicine* 2016, DOI:10.1056/NEJMoa1611593).

BOWEL HABITS OF HEALTHY INDIAN CHILDREN LESS THAN TWO YEARS OF AGE

Shrish Bhatnagar, Geetika Srivastava, Ayub Ansari
ERA'S Lucknow Medical College and Hospital, India
Department of Pediatrics

BOWEL HABITS OF HEALTHY INDIAN CHILDREN LESS THAN TWO YEARS OF AGE (Abstract): **Objectives**: To define the normal frequency and consistency of stools of healthy Indian children between 0-24 months of age. **Material and Methods**: Parents of children aged up to 24 months were asked on a three-day recall basis about their child's usual bowel habits and dietary history. Bowel habit was recorded in terms of number of stools the child passes per day, stool consistency, the age at which night bowel movements stopped, and age of regular bowel movements. Feeding type was recorded as exclusive breast feed, mixed milk feeds or on solid feeds. The bowel habits were correlated with the age of the child and type of feeding. **Results**: Children in first six months of life had stools which were predominantly "pasty" and "runny like cream" with high and variable frequency. Beyond six months of age they had "solid" and "pasty" stools with a frequency of one to two per day. On analyzing the combined effect of type of milk feed and age on bowel frequency and consistency children beyond one month of age either on exclusive breast feed or on mixed milk feed had similar frequency and consistency of stools. By one year of age more than 90% of children had attained regular stool pattern and no night time bowel movements. **Conclusions**: First of its kind study from India which describes the stool pattern of normal healthy children less than two years of age. **Keywords**: BOWEL HABITS, HEALTHY CHILDREN, INDIAN

Bowel habits have been defined previously in literature in terms of frequency and consistency of stools. Many researchers in the past across different regions of the world have studied the bowel habits of children and their correlation with age and type of feed (1-5). Bowel habits of children less than two years are quite varied and there is no definite hard data on stool pattern of Indian children particularly less than two years of age. Parents are unaware of what the normal frequency of stool per day and consistency of stool should be and when should either of them be called as abnormal. Thus the aim of our cross sectional study was to define the bowel habits of healthy Indian children between 0-24 months of age.

MATERIAL AND METHODS

1,196 children aged up to 24 months were recruited from the postnatal wards and good baby clinic of our tertiary care hospital from April 2011 to December 2014. Children were recruited in the following predefined age groups of: 0-14 days, 15-28 days, 1-3 months, 4-6 months, 7 -12 months and 13-24 months.

The following children were excluded from the study group

1. Those suffering from fever, dysentery or any concurrent illness during the time of study.

2. Children who have any gastro intestinal illness or any severe illness requiring medication in last one month.

3. Those with past history of significant chronic medical illness or have underwent any surgery.

4. Children who were born preterm i.e. <37 completed weeks of gestation.

5. Those having weight and height less than the third percentile for the corresponding age.

Informed consent was obtained from the parents. After recording the socio demographic data and anthropometry of the children, parents were asked on a three-day recall basis about their child's usual bowel habits and dietary history. The consistency of stools was divided into1) solid, 2) pasty/soft like peanut paste, 3) runny like cream and 4) liquid like water. The type of diet was divided into three types a) Exclusive breast feed b) Mixed Milk Feeds: Breast feed and top milk feed c) Solid: Children who were started on complementary feed. Before taking opinion of parents they were verbally given the details of each stool consistency item to avoid any misinterpretation. They were also asked about the age at which night bowel movements stopped, and age of regular bowel movements. Interpretation of regular bowel movements was that bowel movements were nearly at same time of day and mothers could predict timing of bowel passage.

RESULTS

A total of 1196 children were studied, out of which 580 (48.5%) were males. Number of children recruited in each age group were 198(0-14 days), 200 (15-28 days), 208 (1-3 months), 200(4-6 months), 200(7 -12 months) and 192(13-24 months). Majority of the parents were from urban setup and had free access to toilet. Primary caregiver was mother to 80% of children. 95% children were born in a health care setup and had received pediatric care at birth.

Dietary History

The dietary history revealed that mixed milk (breast milk + top milk) type of feeding was the predominant feeding in children less than six months of age while solid feeding was the predominant type beyond that age (tab. I).

TABLE I

Feeding pattern of children less than 2 years of age

Age Group		Feeding type		
		Exclusive	Mixed	Solid
1	0-14	184	14	0
2	15-28	88	112	0
3	1-3 months	52	156	0
4	4-6 months	28	128	44
5	7-12 months	8	24	168
6	>13-24 months	0	8	184

Bowel Frequency with age

The mean frequency of stool in each group is given in figure 1. The mean frequency was high and variable in first six months of life and subsequently became constant after six months of age. Only 17% of children less than one month passed fewer than 2 stools per day. Interestingly there were nearly 15-34 % of children beyond one month and less than one year of age who did not pass stools daily.

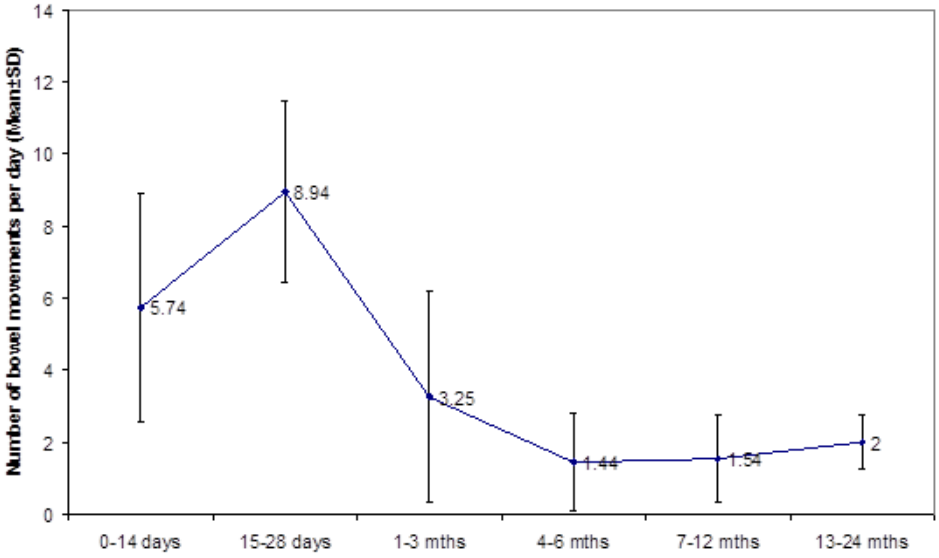

Fig. 1. Mean frequency of Bowell movements in each age group

Bowel Frequency
with various types of diets

It was seen that children who were on exclusive breast feed had highest frequency and variation of stools per day with a mean of 5.56 ± 3.94 (range0-20/day). The mean number of stools of children who were on mixed milk feed was 4.32 ± 3.55 stools per day (range0-12/day) and the children who were on solid feeds had mean stool frequency of 1.64 ± 0.9 stools per day (range 0-4/day).

Bowel Consistency with age

"Pasty" and "runny like cream" stools were the predominant types till six months of age. Beyond six months of age most children passed "solid" and "pasty" stools.

Bowel Consistency
with various types of diets

Children who were exclusively breast fed and on mixed milk feed had "pasty" or "runny like cream" stools while children on solid feeds had predominantly "solid" stools

Combined effect of type of milk feed and age on bowel frequency and consistency

This was assessed in children up to six months of age. In initial few days of life(<15days) children on breast feeding had higher stool frequency but after first month of life children with mixed milk feed and exclusive breast feed had similar frequency of stools per day.

The consistency of stool was similar in both the type of feed pattern. In first month of life it was predominantly "runny like cream" and beyond that mainly "pasty" up to six months of life

Regular bowel movements
and stopping of night movements

Half of children had regular bowel habits by the completed age of six months and almost all (92%) had a regular habit by one year. At age of six and twelve months only 40% and 5% of children respectively had persistence of night bowel movements (fig. 2).

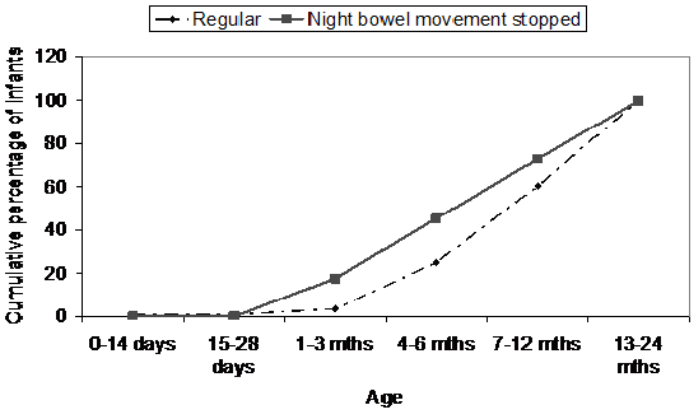

Fig. 2 Pattern of regular Bowel movements and stopping of night movements

DISCUSSION

To our knowledge the bowel habits of healthy Indian children have not been described till now and this study tries to provide an over view of the stool pattern of young children less than two years of age and also correlation with the type of feeds they consume. Studies in past from various countries across globe have been published and on comparison with them we had some interesting observations (1-5).

Maximum numbers of children were on mixed feed pattern in children less than six months. Exclusive breastfed were only 34% which less than the pan India percentage of 46% (6). This is itself a cause of concern and an urgent need for launching special program to promote exclusive breast feeding in the study region

Our study has showed that maximum stool frequency was in early part of life and as the child grew the frequency decreased and almost became static by 12 months of age to 1-2 stools per day. Along with age, type of feed given also did effect the stool frequency of children. Children on exclusive breast feeding had highest frequency and variation of stools per day an observation shared by studies in past (1, 4-5). One interesting observation we found that nearly 15-34% of children between ages of 1-12 months did not pass stools every day. This is deviation from the Australian data which says that only <5% of children did not pass stools every day (5). The reason for this deviation could be because of less percentage of exclusive breast fed infants in our study group. Human milk oligosaccharides which are prebiotic oligosaccharides have shown to have positive effects on stool consistency and stool frequency (1).

Bowel consistency also varied with age. “Pasty” and “runny like cream” stools were the predominant types till six months of age. After that “solid” and “pasty stools” were the predominant stool consistencies. These findings are similar to many studies from the past reflecting the normal physiology of gut development which hasn’t changed over the years (1, 3, 5).

The bowel consistency is also affected by child’s diet. Children who were exclusively breast fed and on mixed milk feed had “pasty” or “runny like cream” stools while children on solid feeds had predominantly “solid” stools. The possible explanations given for this are that gastric emptying time for breast milk is faster than that

of formula milk, difference in intestinal bacterial flora of children on different feeds and levels of circulating peptides which influence the bowel habit are different in infants on different feeds (7-9).

Studies by Stien et al, Jaffe et al and Thompson et al 1998 have reported that intestine of infants continues to develop after birth and bowel movements decrease during sleep. Hence it's believed that bowel movements become regular as the age of children increase. In our set of children similar pattern was seen and 92% had a regular bowel habit and 95% had stoppage of night bowel movements by12 months of age (10-12).

Our study gives an overview of stool pattern of children less than two years. However, India being ethnically diverse country with different child rearing practices a large multicenter pan India will give a better understand of stool pattern of normal children of same age group.

CONCLUSIONS

To conclude our study tries to define the stool pattern of normal healthy children less than years of age in terms of stool frequency, consistency and its association with feeds. This study will help all pediatricians to be aware of what normal stool habits is will in turn help in better management of children and counselling of parents in their day to day practice.

ANATOMICAL AND CLINICAL ORBSERVATIONS ON STRUCTURAL CHANGES OF THE HIP JOINT

Luana-Andreea Macovei, Elena Rezus
University of Medicine and Pharmacy "Grigore T. Popa"-Iasi
Faculty of Medicine
Department of Medical Specialties (II)

ANATOMICAL AND CLINICAL OBSERVATIONS ON STRUCTURAL CHANGES OF THE HIP JOINT (**Abstract):** The hip, the second largest joint of the human body, with its primary contribution to locomotion, is exposed to numerous traumatic or non-traumatic risks. Regardless of the initial pathology, there is always almost the same result: diminution of range of motion, onset of pain and functional impotence, as well as change of biomechanics of walking. Through its high frequency, morpho-functional imbalance (clinically expressed both imagistic and biologically, in one or several joints), osteoarthritis is a disease with a multifactorial etiology and a complex pathogeny. **Material and method**: The study included 244 patients aged between 18-85 years, clinically and paraclinically investigated, especially for the osteoarthritis of the hip, admitted to Rheumatology Clinic I, Rehabilitation Hospital in Iasi, from January 2012 to December 2014. **Results and Discussion**. The high prevalence of degenerative diseases of the joints in old age is analyzed in accordance with the results of the estimations, which showed that, in fact, most of the patients remain undetected, undiagnosed and untreated. Main symptoms are pain in the coxofemoral joint, radiating or not on the lateral or anterior face of the thigh down to the knee, morning stiffness after a long rest, limping or walking with small steps, and muscle atrophy of the group of muscles that are responsible for the stability of the joint. **Conclusions**: A strict discipline is needed from the patient's side, in order to keep and apply the doctor's indications in a chronic disease that requires a long therapy, on one hand; on the other hand, a close cooperation between various experts is needed, in order to customize and apply the most effective program, at the right time. **Keywords**: OSTEOARTHRITIS, DEGENERATION OF CARTILAGE, BONE RECONDITIONING, FRACTURE.

The human locomotor system contains structures of the body that, through complex interactions between components and between components and the environment, generate support and movement of the body. Anatomically, a joint is a system made of passive and active components (1).

The hip joint (coxofemoral joint) is a synovial joint that connects the femur bone (femoral head) and the basin of the skeleton (acetabular cavity). It has the form of a typical spheroidal joint, a triaxial enarthrosis with a ligament transfer found at the area between the trunk and the free lower limb, with three axis of movement. When in orthostatic position and resting on both pelvic limbs, the femoral head is loaded under compression (2). As it rests on both

femoral heads, the basin needs only very small muscle forces for frontal stabilization. The body weight is directly and evenly distributed on both lower limbs. The following movements are made at the hip joint: flexion - extension, abduction - adduction and internal rotation - external rotation (3).

Friction and / or wear may occur as a result of the relative movement between the joint parts. An increase in wear or deterioration may also be due to changes in the synovial fluid or cartilage (4).

Hip osteoarthritis is joint damage caused by an interdependence between the morphological and functional imbalance. It is the most common hip disorder, a painful chronic arthropathy, a progressive and highly disabling disorder, with higher prevalence in males, that limits the static and dynamic status of a person as well as the self-care routine activities.

The common goal of all forms of treatment is to break the progressive pathogenic chain of the disease in order to create conditions for regeneration of the joints.

The purpose of this paper is to evaluate the possibilities for diagnosis and treatment, considering the fact that the radiological examination is essential during diagnosis, monitoring, progress, and the options for therapeutic indications.

We used ANOVA test for descriptive statistical analysis (*t*-Student) quantitative significance to measure variability and the weight of the observations. The data base was managed in Microsoft Office Excel, while the statistical analysis was made in MedCalc and Epi Info 2000.

MATERIAL AND METHODS

The study group was randomly chosen; the data were collected from the patient charts, and the patients were interviewed through a questionnaire.

The study was conducted on a group of 244 patients aged between 18 and 85 years, assisted in Rehabilitation Hospital in Iasi, Rheumatology Clinic I, from January 2012 to 31 December 2014. The selection of the group was based on inclusion and exclusion criteria. The method consisted of statistical analysis of results obtained by analyzing the patient charts, considering: background, age, gender, onset symptoms, risk factors, radiological manifestations, type of recommended treatment, response to therapy, treatment – induced toxicity, as well as the quality of life.

We included the measured height and weight, abdominal perimeter (normal if less than 94 cm in men and 88 cm in women), calculation of body mass index, reading of blood pressure and pulse. The investigations also included EKG, paraclinical tests (level of serum glucose, cholesterol and HDL – cholesterol, triglycerides, highlighting the inflammatory syndrome – ESR and CRP). The anthropometric measurements revealed obesity in 179 cases of women (73.36%) and 51 (48.2%) cases of men.

Concerning the climatic factors, 74 (30.32%) cases complained of the aggravation of symptoms due to environmental changes. Occupational risk activities were revealed in 8.60% of patients operating with vibrating instruments or performing running or horse riding.

RESULTS

The hip pain is a chapter in pathology with great significance for medical rehabilitation, since its prevalence is higher and higher, asking for expert's involvement in a complex and effective treatment.

Hip osteoarthritis met in adults over fif-

ty years old and in seniors, with an equal prevalence in both genders, is the main cause of disability and prosthetics in elderly (5,6,12). The patients benefit from a complex and long lasting therapeutic scheme, in two stages: a medical one, conservative, combining hygiene of the joints, drugs and maintenance or functional reeducation physical therapy, and a surgical stage (6,7).

Most often, degenerative pathology of the hip shows in 57-79 age group. The age, with morphological and functional changes it induces in this structure, has a major role in setting of the degenerative process. 187 patients (76.63%) came from urban settings and 57 patients (23.57%) from rural setting, predominantly from urban setting, with a high statistical difference ($p < 0.005$).

The major symptom of the disease was pain, felt in the inguinal area, frequently radiating on the inner side of the thigh, more intense around the knee, on the lateral or posterior side of the lower limb, without extending the lower third; to a great extent, the pain was felt almost continuously with nocturnal recrudescence and morning stiffness.

174 (71.31%) cases were males, while 7 cases (28.69%) were females; the difference is statistically significant ($p < 0.005$).

There were cardiovascular comorbidities in 49 patients (20.08%), respiratory - 11 patients (4.52%), gastrointestinal - 24 patients (9.83%), osteoarticular - 51 patients (20.90%), neurological - 14 patients (5.73%) and other comorbidities - 95 (38.94 %).

In some forms of osteoarthritis, the genetic blueprint may be considered, which in our case is present in 71% of the patients, who reported a degenerative articular disease in first degree relatives.

Pathological personal antecedents of the cases are: fractures - 74 cases (30.32%), luxations - 34 cases (13.93%), meniscal injuries - 13 cases (5.34%), hemarthrosis - 17 cases (6,98%), synovitis - 21 cases (8,60%), metabolic and endocrine diseases - 18 cases (7.39%), rheumatoid arthritis -19 cases (7.78%), neurological diseases - 9 cases (3.68%), circulatory disorders - 39 cases (15.48%) (table I).

TABLE I

Presence of pathological antecedents in patients enrolled in the study

Antecedents	No.	%
Fractures	74	30.32
Circulatory disorders	39	15.48
Luxation	34	13.93
Synovitis	21	8.60
Rheumatoid arthritis	19	7.78
Metabolic and endocrine diseases	18	7.39
Hem arthrosis	17	6.98
Meniscal injuries	13	5.34
Neurological diseases	9	3.68

As found in other authors (9,12), we discovered that fractures were the most frequently involved in etiopathology of osteoarthritis (30.32%), followed by peripheral circulation disorders (15.48%) and luxation (13.93%).

In most of the cases, the diagnosis of hip osteoarthritis is facilitated by a careful anamnesis, which points out to the onset of the pain, location, radiating pain and by the physical examination of the patient. The onset of the disease is insidious; for many patients it starts as fatigue of the coxofemoral joint after a long static or dynamic activity. Pain is the main symptom in all primary or secondary forms of disease; patients experience the symptom spontaneously and in motion, in groin, retrotro-

hanterian or gluteal area. Some patients report pain on the knee ("the cry of the hip"), or, as *Lequesne* notices, knee pain might be the only expression of hip involvement (5).

The pain is mechanical, the patient presenting an antalgic gait, shortening the duration of leaning against the affected part. The limping appears, caused by muscle insufficiency of the middle gluteal muscle, while in advanced phases, the patient displays an obvious vicious attitude. The most damaged muscle groups are the extensors and the abductors of the thigh due to the biomechanical changes during gait and to the decrease of their physical demands. Muscular analysis of thigh was required by major hypotonic in thigh and especially in the *gluteus medius* muscle, known as the muscle which is mostly prone to hypotrophy in case of inactivity. This results in gait waddling on one side due to the disturbance of the muscular balance of the basin, changing the parameters of gait.

Physical examination, performed in orthostatic, in static and dynamic position and in decubitus, shows at inspection, touch, percussion and examination of mobility the following: vicious position of the lower limb and trunk, amyotrophia, muscle contraction of abductor muscles, pain during direct percussion of the great trochanter, shortening of the pelvic limb, disorders of the statics of the spinal cord.

During physical examination of the hip, we noticed the predominance of objective signs that concerned synovia, in spurt flares and pain during mobilization of the joints. The walking perimeter varies a lot among patients; 132 cases (54.09%) still have a walking perimeter over 500 m.

Special tests of assessing the degree of affecting the articular mobility were made in 137cases (56.14%). Positivity of special tests on hip mobility were: Patrick test – 59 (43.06%) cases, Trendelenburg test - 41 patients (29.92%) cases, Thomas test - 21 (15.32%) cases, Ober test - 16 (11,67%) cases (fig. 1).

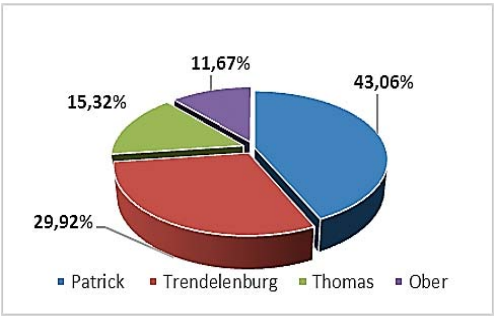

Fig. 1. Positivity of special tests on hip mobility

Non-specific inflammatory tests (ESR, CRP etc.) were positive in 41 (16,80%) cases.

In case of our research, similar to other authors' research (9,11), the early diagnosis of hip osteoarthritis was made through special investigations: ultrasonography in all 244 cases, CT in 71 (29.09%) cases, IRM in 64 (26.22%) cases, arthroscopy in 29 (11.88%) cases (fig. 2).

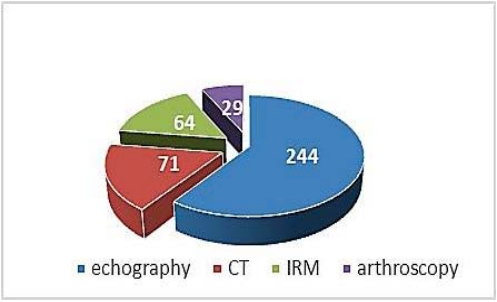

Fig. 2. Special tests were made in early diagnosis of hip osteoarthritis.

IRM imagistics is better than radiography and CT when assessing cartilage integrity and cephalic contour, with indications in early stages of the disease.

Radiography is the first line examination. Anterior-posterior and lateral radiography of the basin in orthostatic position are used to exclude other causes of coxopathy and also to make a coxometric evaluation and to show the degenerative changes in the hip joint and in the proximal joints, in the lower lumbar spine and in sacroiliac joints (7).

The radiological semiology of hip osteoarthritis was characterized by the following changes in the studied cases: narrowing of the joint interline (which seems to be the most accurate assessment tool of the stages of hip osteoarthritis, showing the progressive destruction of joint cartilage) (8). Radiologic changes were present almost constantly; reduction and even disappearance of joint space -159 (65,16%), sclerosis of subchondral bone in 48 cases (19.67%), osteophytes - 8 (3.27%), geodes -2 (0.81%), subluxations -12 (4,91%), erosive phenomena - 11(4.50%), ankylosis – 4 (1.63%) cases.

In 1982, *Baird* et al. (see reference 9) confirmed the value of CT after hip luxation, detecting the intraarticular fractures.

Ultrasonography brings guidance, since joint is difficult to approach and it is used as a special means, "the extension of the clinic exam", but the hip joint is deep and difficult to access.

The intensity of the primary degenerative process was: first degree - dubitable osteoarthritis, 12 (4.93%), second degree - minimal, 136 (55.73%), third degree - mild, 74 (30,32%), fourth degree - severe, 22 cases (9.02%) (fig. 3).

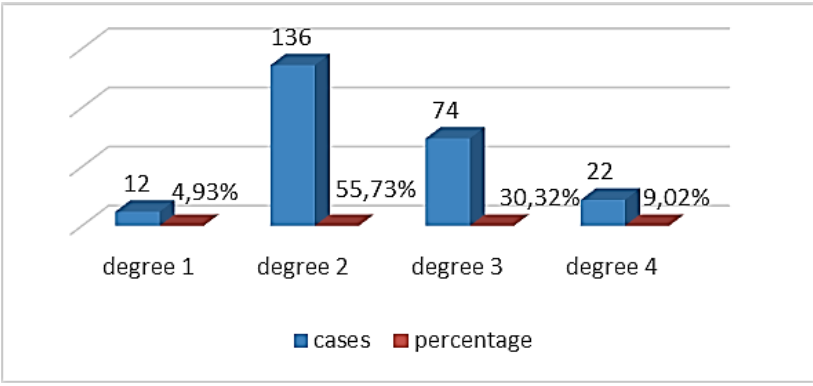

Fig. 3. Evaluating the degree of the primary degenerative process

Treatment: The patient usually follows two therapeutic stages. The first stage is the conservative treatment that delays the development of the disease and maintain an acceptable functional status by using a multidisciplinary approach: drug therapy, physiotherapy and orthopedic rehabilitation. In the second stage, the morphological and functional damage leads to surgery mostly in the form of joint prosthetics. At this stage, is estimated that the optimal age for prosthetic rehabilitation is after the age of 65.

Conservative treatment aims to relieve

pain, to improve the functional deficit and to slow the progression of the disease. The conservative therapeutic methods are pharmacological and non-pharmacological. Pain and inflammation were relieved with antalgic, anti-inflammatory and muscle relaxing drugs. Pharmacotherapy was used in 139 (56.96%) cases, and 74 (30.32%) subjects had a pluridisciplinary treatment.

The initial antalgic treatment included acetaminophen 0.5-1 g every 6-8 hours, without exceeding the maximum doze of 3 g per day, while AINS were used as anti-inflammatory drugs (diclofenac, piroxicam or meloxicam).

In hip osteoarthritis, the local infiltrations were avoided because corticosteroids have a transient effectiveness, increasing the degradation rate of the articular cartilage.

Electrotherapy and physical therapy were used as non-pharmacological therapy.

The pharmacological treatment was accompanied by adverse reactions, such as: gastric pain – 56 (22.95%) cases, nausea – 72 (29.50%) cases, vomiting – 12 (4.91%) cases, constipation/ diarrhea – 7 (2.86%) cases, headache, vertigo – 9 (3.68%) cases, allergic reactions – 10 (4.09%) cases, anemia/ leucopenia/ thrombocytopenia – 18 (7.37%) cases, increase of blood pressure – 13 (5.32%) cases and no side effects – 47 (19.26%) cases.

The non-pharmacological methods of rehabilitation are electrotherapy, massage, thermotherapy, hydrotherapy, balneotherapy and physiotherapy.

The rehabilitation program included electrotherapy that has an analgesic and excitomotor effect and stimulates local circulation in 15 cases (6.14%). The massage was performed in 45 patients (18.42%) through analgesic decontractive applications used to stimulate local circulation and tone the deficient muscle groups, providing a real benefit to the patient.

The design of a physical therapy program for hip rehabilitation considered that the joint provides the monopod and bipod support joint in statics and dynamics forming with the pelvis a functional unit. This is possible due to a particular architecture and to an effective muscle apparatus for achieving the pelvic-femoral balance. The physical therapy program was made according to the clinical, radiological and functional evaluation and it was adjusted depending on comorbidities.

Physical therapy was performed in 84 (34.42%) cases, involving various procedures for muscle strengthening, torn muscle relief, asuplisation of capsular ligaments, and exercises for increasing the joint amplitude.

The physiotherapy program used in the study group provided an effective relief of pain, changes of vicious attitude of flexion, adduction and external rotation, the increase of joint range of movement and muscle strength, the rehabilitation of dynamic muscle control in walking, the ability to perform certain daily activities, so that the patient's quality of life is highly impacted.

The outcome of the rehabilitation programs, namely the improvement muscle strength in the basin area, led to a limitation of tilting movements during walking. This limitation was functionally shown by the relief of limping, even if it was not permanently removed.

The surgical path is used for inserting hip prostheses through minimally invasive methods and it has been extensively studied over the past decades. The minimally invasive methods have a less impact on the peri

- and intra-articular ligamentous structures. Minimally invasive surgery is less aggressive and highly recommended in old patients with chronic diseases, as it allows a much faster functional recovery (11). Limiting surgical and anesthetic risks is very important, especially as the age of patients undergoing such interventions has continuously dropped in recent decades (12). Hip replacement or, in medical terms, total hip arthroplasty, is a successful story in orthopedics as it provides a solution for millions of people with irreparable damage of this joint.

DISCUSSION

The structural changes of the hip and particularly the functional changes, such as the onset of pain, muscle contractures and / or retractions contribute to the limitation in the mobility of the coxofemoral joint.

In the study group, the onset of pain in the affected hip led to the development of poor habits and bad static and dynamic postures. Body weight was automatically distributed on the healthy lower limb and the healthy joint was overloaded. This habit represents a bad motor engram that changes the normal gait. The gait becomes limping and support appears and a change in step times. The deviation of the center of gravity to the front is significantly higher in patients experiencing pain in the coxofemoral joint than in patients free of these disorders.

A rigorous and comprehensive biomechanical analysis of the hip joint can provide important additional information for the complex preoperative assessment, leading to a future therapeutic approach.

The study group consisted of 244 patients, most of them aged over 65 years, mostly originating from urban settings (76.63%). During physical examination of the hip, there were objective signs that concerned the synovial part and mobility pain.

Wright (11) describes a syndrome that destroys the femoral nucleus, related to poor blood supply of the upper femoral epiphysis. *Jacques Calve* (12) published in "Surgery Journal" a monography, entitled "On a particular form of pseudo-coxalgia associated with a characteristic deformity of the upper end of the femur". The author describes the disease clinically and radiologically, excluding the traumatic and infectious etiology.

The importance of the hip "discharge" increased gradually due to research conducted by *Waldenstrom* and *Danforth* (12). *Catterall*'s radiological research is remarkable (17). The external epiphyseal fracture was described by Fergusson, consisting of separation of an external fragment from the epiphyseal nucleus, a consequence of the external epiphyseal surplus (19).

Lawrence (11) showed that in subjects between 15-24 years old, the degenerative lesions pointed out by X-rays are present in 10% of the cases, compared to 80% in age groups over 55 years.

Compared to our study, the regularity of the femoral head is appreciated radiologically by concentric circles, placed at 2 mm distance, conceived by *Mose* (11); articular surface index, first used by Meyer, offers information about the morphology of the head; it is the ratio between the height of the head and its diameter (18).

Trueta (9) believes that osteoarthritis is secondary to high blood pressure in the hip joint, influencing this way the nutrition of the cartilage. Intraarticular forces will cause loss of elasticity connective tissue,

degenerative and necrotic phenomena in the areas where they act.

De Sèze and *Duriève* (12) believe that some vascular processes that influence the trophicity and metabolism of joint structures may cause hip osteoarthritis. *Rutishauser et al*. suggest that venous stasis has an important role in the development of osteoarthritis.

Axaser suggests that the chondrolysis process can occur due to damaged blood circulation in the subchondral area (9). *Pommer and Lang* show that this disease is the result of a dynamic imbalance between cartilage resistance and loading forces. This leads to severe changes in the physiological properties of the cartilage. This mechanical functional theory explains the presence of marginal osteophytes, bone products caused by improper mechanics (11).

Trueta explains the predominance of the fractures in 56 male patients (22.95%) (14) by traumatic factors that act in this period. *Chung* (11) explains this predominance in males by a particular vascular structure, unproven, but experimental.

Worldwide, osteoarthritis is the most frequent muscular-skeletal disease, affecting population over 55 years of age *Hinman, Hezwood* (11), while future forecasts predict a significant increase of incidence and severity, with particular implications for the health of the population.

The mechanical theory of *Freeman* (12) attributes the degenerative process to fracturing of collagen fibers.

Ficat (11) divides the disease into mechanical, structural, inflammatory and infectious chondroses, according to the condition and etiology of the destructive processes.

CONCLUSIONS

Our observations revealed the high frequency of fractures – 74 (30.32%) cases after 60 years of age, proving the fact that degenerative osteopathy is an old age disease; most of the subjects came from urban settings – 187 (76.63%) cases, with an easier access to health care services.

At study enrollment there were the following comorbidities: 49 (20.8%), respiratory -11(4.52%), gastrointestinal - 24 (9.83%), osteoarticular - 51(20.90%), neurological - 14 (5,73%), other - 95(38, 94%) cases.

We were able to identify at least one risk factor that could be incriminated in the etiology of the degenerative disease in all patients: fractures -74 (30.32%), luxations - 34 (13.93%), meniscal lesions -13 (5.34%), hemarthrosis – 17 (6.98%), synovitis – 21 (8.60%), endocrine and metabolic disease – 18 (7.39%), rheumatoid arthritis - 19 (7.78%), neurologic diseases - 9 (3.68%), circulatory disorders - 39 (15.48%) cases.

As for radiological investigation, we concluded that it has an important role, facilitating the diagnosis, without being indispensable.

Although not lacking side effects, the pharmacological treatment contributed to pain relief in patients with degenerative hip pathology who face an important degree of disability (pain, vicious position, walking perimeter). The rehabilitation of joint mobility must be associated with the rehabilitation of strength in muscles that perform these movements.

It became obvious the fact that a therapeutic, educational, medicinal and physical combination is able to control the patients' sufferance from the onset of the disease, in an effective patient-physician cooperation.

THE MALFUNCTIONS OF A NATIONAL TRANSPLANTATION SYSTEM: MULTI-LAYERED EXPLANATIONS FROM WITHIN (Abstract): Romania has one of the lowest posthumous organ donation and transplantation rates in Europe. **Aim**: To explore the perspectives on the national transplantation system deficits shared by the physicians responsible for the identification and referral of potential posthumous organ donors. **Material and methods**: The study consists of semi-structured interviews with the key informants (ICU physicians, neurologists and neurosurgeons) in county hospitals in Moldavia. **Results:** The explanations for the current Romanian organ transplantation rate, as emerged from the participants' answers, are multi-layered. Overall, the national transplantation system is accused of being plagued with serious problems: it is underfunded, understaffed, its resources have been distributed unevenly among medical centers, the communication between its elements is disrupted, leaving the majority of the transplant professionals practically detached from its upper layer and affecting their motivation to perform their transplantation-related tasks. Furthermore, some of the participants point to the strong reluctance of the population to donate their deceased relatives' organs. **Conclusions**: The results suggest a set of possible multi-level interventions that could alleviate these problems. **Keywords**: TRANSPLANTATION, ORGAN SHORTAGE, TRANSPLANT SYSTEM, HEALTH PROFESSIONALS, POPULATION, ROMANIA.

There is a universal shortage of cadaveric organ donors; while the number of patients waiting for transplants continues to increase, organ donation rates remain low. These rates vary widely between countries, Romania ranking near the bottom of the European hierarchy, with 3.6 deceased donors per million of the population in 2009 (1). Only 31% of the Romanians would agree to donate their organs after death and 34% would consent to donate organs of a deceased family member, far below the European means of 55% and 53% respectively (2).

An important factor influencing the posthumous organ donation rates is the refusal of the bereaved families to give consent for donation and the public's reluctance to donate (3). The attitude of the health professionals towards organ dona-

tion and transplantation, as well as their knowledge on these issues, also influence the decision to donate of the family members (4, 5). Their influence is not limited to the conversation with the family members, but it extends to their own involvement in terms of identification and referral of potential organ donors (6, 7).

In addition, the characteristics of the national transplantation system influence the work of the health professionals involved (8, 9) and, consequently, the number of donated organs. Among others, the technological level of the available medical facilities, the adequacy of personnel training or the degree of articulation between the various levels of the medical system can hinder or stimulate the efficiency of the transplantation system.

The aim of our study was to explore the perspectives of the physicians involved in the identification of potential organ donors on the factors influencing the functioning of the Romanian transplantation system and on the available interventions that could limit the negative influences.

MATERIAL AND METHODS

We used a qualitative methodology based on semi-structured interviews with open-ended questions. The participants were physicians of one of the three specializations involved in the diagnosis of brain death (neurology, neurosurgery and ICU) working in hospitals from the Moldavian counties, and responsible for the identification and referral of potential brain death donors. 24 physicians were contacted; 17 agreed to participate (10 men, 7 women): 6 neurologists, 6 neurosurgeons and 5 ICU specialists. The participants' age ranged from 41 to 57 and their work experience from 3 to 19 years. The interviews lasted about 50 minutes each and were all recorded.

The study was approved by the Research Ethics Commission of the University of Medicine and Pharmacy "Grigore T. Popa"- Iaşi. All participants were informed about the aim and procedures of the study and freely consented to be enrolled.

The interviews were transcribed verbatim, and analyzed in a grounded theory approach. The interviews were coded using the county name and the medical specialty abbreviation (N- Neurology; NS- Neurosurgery; ICU- Intensive Care Unit). In order to access and explore the essential meanings of the answers, the constant comparative analytic procedure was employed, by first reducing them to concepts through open coding. Then, we explored the associations between the various categories in different parts of the textual data. Each hypothesis that emerged across this coding process was compared to the new statements in participants' answers, thus assessing its validity. When the meanings of the new statements differed from the previously established relevant hypotheses, the latter were reformulated in order to accommodate them. When the differences were too large, indicating the existence of distinct perspectives on the same issue, the new meanings were theoretically condensed into a new partial hypothesis.

RESULTS AND DISCUSSION

The inner problems of the Romanian transplant system

The participants pointed out several categories of inner problems, distributed on several layers, from the individual one, the human resources employed in the system, to more general, organizational issues. On the first layer, some of the respondents identified the health professionals' low

motivation. On one hand, their involvement in the transplant- related interventions is an additional task, interfering with the already busy daily work schedule:

"It is an extra activity and the not so numerous employees already have to cope with a busy schedule. It is natural for interest in such activity, that we consider collateral, to be reduced" (NS1).

Therefore, the level of effort invested in the organ transplant– related tasks is low:

"I think it is also about our lack of involvement" (NS2).

A possible solution to this motivational issue is, for some participants, the financial retribution of their involvement in the transplant- related tasks.

"Those in charge of transplants should be paid more, no doubt about it!" (ICU5)

On the other hand, the low external rewards of the physicians could be compensated by their internal motivation, grounded in the life-giving character of transplantation. The satisfaction stemming from saving the life of the organ recipient can help them rationalize the efforts they had invested in the lost cause of saving the life of the deceased donor:

"We often struggle for patients who we know to have little chance, and we see no solution, but maybe it is then we get a new one, a new meaning…of all the work invested. Despite the end of that particular life, a new one might continue" (ICU2).

This type of approach involves the health professional's concern for the welfare of the potential organ recipient. Altruism appears to be an important factor for the health professionals' approach on organ donation (10). However although altruism should be at the heart of the medical profession, its current practical relevance is diminished. This issue would require educational interventions directed to physicians, such as development of campaigns aimed at stimulating their altruistic tendencies as motivators for their involvement in the organ transplant- related tasks:

"I say 'education' because we should get involved in this field of activity selflessly, as a result of our belief. In the long run, this is our purpose in medicine, or at least it should be" (ICU1).

Beyond the motivational issues, some physicians point to a systemic dysfunction in the informational circuit between the levels of the Romanian transplant system. Its main consequence is the informational deprivation of the physicians, not only in terms of their scientific update on the relevant medical issues, but also concerning the basic statistics of the outputs of this system:

"Not even us, the doctors, have knowledge of the number of kidney transplants performed in Romania so far, as well as their consequences" (N2).

The limited personal experience of many physicians with organ transplantation- related procedures can influence their attitude towards organ donation and gradually instigate further reticence among this first and essential layer of the Romanian transplant system. Other studies reveal that an important variable in this respect is health professionals' amount of personal experience with managing and referring brain dead patients (11). On the other hand, even when potential donors are identified in these "lower level hospitals", the lack of feedback on the successful transplant procedures that are performed elsewhere further induces a sense of futility regarding their efforts. Providing follow-up information on organ recipients could prove an effective intervention in order to raise the

level of support for and involvement in transplantation- related tasks among these health professionals (12).

An explanation for the scarcity of the information transmitted to the lower levels of the system is the traditional, and still ongoing, status of transplant interventions as high-end procedures, reserved to a select group of professionals:

"The specialized literature has not presented this side of the transplant as a real treatment possibility, but more like some sort of performance...reserved to a limited number of doctors, having experience, conditions and so on...even now this topic is still viewed as high performance or excellence in medical practice" (N3).

At present, this situation is perpetuated by the insufficient funding only covering the organ transplant- related expenses of the large medical centers:

"Large centers alone have this possibility. Funds were granted and still just the first layer benefited from technology, money and specialists" (ICU1).

Another consequence of this lack of articulation of the transplant system is the deficient communication between its various levels on current relevant issues:

"I think the most important problem is the lack of communication between ICU and the donation team" (ICU4).

Given the fast-paced nature of the set of procedures required by organ retrieval, these communication issues hinder their success, even causing failures in potential donation cases:

"There was a case here in which everyone stuttered: who's responsible for transplant, who's the one doing this, who's the one doing that… when things were finally clear, it was too late" (NS 1).

The lack of adequate funding is a serious issue, invoked by all our respondents. It affects the performance of the transplant system in two ways. First, it leads to dramatic shortage in the necessary technical equipment, limiting, in some cases, the available transplant- related procedures:

"There is also a deficit concerning the county hospitals equipment, necessary for brain death diagnosis and for maintaining artificial ventilation. They are very scarce in ICU, where the priority is set on the patients with a higher chance of survival." (NS6).

Second, the insufficient funding creates personnel insufficiency, limiting the tasks that the medical staff can perform and, consequently, their involvement in the transplant- related procedures. Furthermore, these insufficiencies raise ethical challenges regarding organ transplant-related procedures, since they require the exclusive investment of a considerable part of these scarce resources, affecting the medical care offered to the other patients:

"If I have two nurses on my shift, one should see to the special care of the donor, which is highly unlikely, since I wouldn't know what to do with the other severe patients in the department. This would not be fair to the other patients." (ICU5)

Subsequently, the cost – benefit analysis of the current situation questions the overall utility of organ transplantation, especially in the hospitals that do not perform actual transplant interventions, but should merely identify potential donors.

Overall, the current under-financing of the medical system as a whole seriously affects the rationality of the transplantation sub-system. The lack of involvement of hospital professionals in the transplant-related tasks appears as a way of defending the functionality of the rest of the system,

focused on providing medical care to the sick, by not deploying it of the already scarce resources:

"If you don't have the money, you do not perform transplantations. The transplant procedures become possible when the system is fit for it. If you don't even have the foundation, you can't perform transplantations, it's as simple as that" (N2)

Nevertheless, in line with the issue of the uneven distribution of resources, some participants remarked the paradoxical character of the Romanian transplant system, mirroring the entire medical system. This paradox stems from the massive differences not only in funding, but also in specialized education and experience between the two levels of the system: the "closed circle" of the first-layer medical centers and the rest of the hospitals:

"[..] again, this is a reflection of the Romanian medical system, with very competent peaks and the contrasting rest of the medical mass, struggling for survival, due to the lack of personnel, equipment, funds and so on." (N3).

In order to alleviate these structural problems, the Romanian physicians mostly prescribe top-down interventions: higher financial investments at all the levels of the transplant structure and the increased democratization of the system. Generally, the experience of other countries (9) shows that organizational improvements can increase the efficiency of the transplant system and, ultimately, the organ transplantation rate.

The attitudes of the general population toward organ donation

The reluctance of the general population to consent to organ donation from their deceased next of kin is frequently invoked as a major cause of the shortage of available organs for transplantation in many countries (13). Our participants pinpoint several factors contributing to the public's reluctance that have been identified by other investigations as predictors of people's willingness to donate. An important such factor is the lack of information on the topics of brain death and organ transplantation (14), which causes difficulties in explaining the diagnosis of brain death to the bereaved families (15):

"The public's lack of knowledge concerning transplantation is a frequent difficulty in discussing donation with the potential donors' families." (NS5)

The general lack of information is attributed by our respondents to the low involvement of the media in popularizing this topic:

"No kind of lobby for transplants, no mass media popularization, neither scientific, nor in terms of popular medicine have been made." (N2)

Moreover, the rare media reports of transplantation cases led to the perception of this procedure as an exceptional and unavailable medical option:

"People perceive this kind of procedure simply as an accidental performance." (N6)

Thus, a possible way to change people's attitudes toward organ donation is the more frequent media coverage of transplant interventions and organ donation. More extensive media coverage of this topic would alleviate the current "eccentricity" of organ transplantation in the public perception, which, in its turn, would positively influence people's attitudes. This idea is supported by previous results (16) showing that social advertisement of organ donation increases the occurrences of the organ donation topic in the discussions among fami-

ly members.

Another factor of the frequent reluctance of the Romanians to donate the organs of their next of kin, identified by some of the participants, is their low levels of altruism:

"My kin died, let others die, too! This is simply selfish and absurd!' (N1).

While altruism has long been recognized as an important internal motivator in these circumstances (17), it is usually conceived as a global orientation towards other people in general, close to the notion of 'humanitarian impulses' (18). However, the psychological deficit criticized by the health professionals in our sample mainly concerns the Romanians' "*lack of civic sense*" (N2), their lack of interest in the welfare of their peers. This perspective moves the reference point in the definition of altruism from the global level to the strictly national one and suggests that deeper issues in the area of the Romanians' collective identity could function as deterrents of the public's willingness to donate. Some of the participants suggested that media should take on a third mission, besides informing and raising awareness of organ donation, that of stimulating people's general altruism.

"Those more likely to donate have certain pieces of information and an open mind" (ICU2).

Finally, another factor identified by the participants as generating the high organ donation refusal rates in Romanian is the low level of trust that people have in the medical system as a whole. As a result, the relationships between the health professionals and their patients are frequently impaired by the latter's suspicions regarding some hidden personal interests of the former. Consequently, the requests for the donation of their deceased relative's organs are met with reluctance:

"The patient coming to the hospital already feels that everybody is a thief and wishes him no good, and those who trust what we know we must do are fewer each day." (NS5)

Moreover, the physicians working in the smaller hospitals have to deal with yet another type of suspicion, concerning their professional skills. Due to their mistrust in the medical competence of the hospital representatives, many of the relatives of brain dead patients withhold their consent, refusing the disconnection of the artificial life-support systems:

"People don't really trust us around here, at least not enough to consent to disconnect their kin from the life support system." (NS6)

Medical mistrust has been confirmed by previous studies as a significant predictor of attitudes towards organ donation (19). Due to its ubiquitous character highlighted by the physicians confronting it, our results suggest that it could dramatically influence the Romanians' stances on this topic.

CONCLUSIONS

Our study shows that the Romanian transplantation system is plagued with serious problems. It is underfinanced, understaffed, the resources being distributed unevenly among medical centers. The communication between its elements is disrupted, leaving the majority of the physicians practically detached from its upper layer, of those performing actual transplant procedures. Consequently, these physicians' motivation to involve in the tasks that are reserved for them by this undemocratic state of affairs is affected. At the same time, a clear set of possible interven-

tions at various levels can be inferred. First, organizational changes are mandatory, not only larger financial investments, but also stronger articulation of the various levels of the transplantation system. The latter would mainly entail increasing the communication between its two current levels- the medical centers performing transplant surgeries and those responsible only for the identification and referral of potential donors- as well as narrowing of the gap between them in terms of information, resources and, ultimately, surgical procedures performed. Second, media campaigns are called for in order to fill the public's massive knowledge gaps on the organ donation and transplantation and to stimulate people's altruistic perspectives on them. In addition the transplantation system could also benefit from campaigns addressing the health professionals' intrinsic motivations to involve in transplant-related tasks.

PROSPECTIVE ANALYSIS OF 55 CASES OF TUBERCULOSIS MENINGITIS IN NORTH INDIA

Tuberculosis meningitis (TBM) is a serious public health problem in developing countries as it leads to significant mortality and residual neurological sequelae. Despite being an endemic country for TB, data regarding clinical, radiological and laboratory (biochemical and microbiological) parameters and final outcome of adult TBM patients is sparse in India. Analysis of such variables in various countries has shown association of various factors with the prognosis of the disease like age, stage of disease, level of consciousness, presence of extraneural TB, isolation of *Mycobacterium tuberculosis* from CSF, biochemical studies and hydrocephalus. The availability of such data in a high developing country may help in prediction of the prognosis of such patients and help in early intervention of preventive measures to improve the subsequent outcome of the patients. In conclusion, TBM is a serious extrapulmonary form of TB and should arise suspicion in mind of clinician based on clinical, laboratory and radiologic results. The present work was planned to frame a model for prediction of mortality in TBM cases by including variables of age>40 years, past history of tuberculosis (TB), presence of basal exudates and hydrocephalus (Kaur H, Sharma K, Modi M, et al. Prospective Analysis of 55 Cases of Tuberculosis Meningitis in North India. Journal of Clinical and Diagnostic Research. 2015, Vol-9(1): 15-19).

EGFR MUTATIONS IN NON-SMALL CELL LUNG CANCER: LOCAL EPIDEMIOLOGY AND CLINICAL IMPORTANCE (Abstract): **Introduction:** Lung cancer's dismal prognosis led to new therapeutic approaches among which TKIs being among most promising; **Material and method:** Retrospective study at the Regional Institute of Oncology Iasi of non small cell lung cancer patients which underwent molecular investigations between November 2013 – September 2014. EGFR mutation status (positive, negative, undetermined) was assessed with an Entrogen EGFR kit using DNA extracted from paraffin embedded samples (surgical or endobronchial biopsies) with the Macherey-Nagel "NucleoSpin FFPE DNAkit" and then amplified on a Applied Biosystem 7500 Real Time PCR System. **Results:** There were 63 adenocarcinoma samples (17 females, mean age 60,9+/-9 years): 49 primary lung tumors and 14 secondary lesions (brain, lymph nodes, pleural). There was insufficient bioptic material for three cases. TTF1 status was determined for 46 patients – six were negative. There were twelve mutations identified (7 female subjects, 5 male) - six L858R, five Del 19 and one G719X; ten were TTF1 positive for the remaining two TTF1 status was unknown. Female sex predominance was statistically significant (p=0.02, chi squared). Mean age for mutation positive patients was 64+/-10 years; there were three never smokers, three active smokers and no data on smoking status was available for six subjects. **Conclusion:** Although small dimension of the study group precludes statistical significance EGFR mutations seem to correlate with TTF1 status. **Keywords**: MUTATIONS, LUNG CANCER, EPIDEMIOLOGY.

Lung cancer is a public health problem being the most important neoplastic cause of death – each year 1.3 million deaths are registered (1). Overall the 5 year survival is less than 15% despite therapeutical efforts (surgery, radiotherapy and chemotherapy either used alone or as a combination).

Non small cell lung carcinoma accounts for almost 80% of overall lung cancers and most predominant subtypes are adenocarcinomas, squamos cell carcinomas, adenosquamos carcinomas and large cell carcinomas. Small cell and squamos cell carcinomas incidence has decreased in the last years for both sexes and many countries presumably because of reduction of tobacco consumption. Presently adenocarcinomas are the most prevalent non small cell

carcinoma subtype (almost 50% of all lung cancer cases) (2).

Lung cancer treatment is dictated by disease stage and patients general health status and comorbidities. Stage I, II and IIIa non small cell lung cancer patients are usually offered a surgical solution frequently associated to an adjuvant therapy (chemotherapy and sometimes radiotherapy); this approach has a reasonable chance of achieving cure (3). However 50 to 70% of NSCLC patients either have an advance stage at diagnosis or relapse after a curative-intent treatment. Standard chemotherapy may improve survival, alleviate symptoms and improve quality of life for these patients. EGFR Tyrosine kinase inhibitors may be a therapeutic option as they may significantly increase relapse free survival and possibly global survival (4). Still, using these compounds require identification of some specific genetic abnormalities that drive tumor development.

Current oncogenetics is considered a discrete process characterized by progressive accumulation of genetic abnormalities involving both oncogenes (promoting tumoral development) and suppressor genes (exercising a limiting effect). Suppressor genes may be classified a "caretakers" and "gatekeepers"; both alleles have to be inactivated to allow tumor development. On the other hand single allele oncogene mutations are sufficient to stimulate cell proliferation. Bioinformatics research show an average of 120 genetic anomalies for a cancer cell. Among those a limited number can be considered driver mutations for tumor development; the others are dubbed silent mutations and their involvement is limited (passenger genes) (5, 6).

There is genetic data suggesting frequent involvement of KRAS, EGFR and BRAF mutations in lung cancer. As well as ALK, ROS1, RET and RON translocations and less frequent newly described JAK2 or ErbB4 (7).

EGFR is a transmembrane protein coded on a chromosome 7 gene (short arm) and belonging to the ErbB receptor family whose members are: HER1/ErbB1 (EGFR), HER2/neu/ErbB2, HER3/ErbB3 and HER4/ErbB4. It consists of a single 1186 aminoacid polypeptide chain. EGFR can be found on the surface of almost any normal cell but it is also intensely expressed on skin and digestive tract; this explains the TKI side effects. EGFR is also largely expressed on epithelial bronchial cells and moderately on alveolar epithelial cells. Three regions may be described – an extracellular one involved with ligand interaction; a transmembrane region characterized by hidrophoby and an intracellular region associating tyrosine kinase activity (8).

Inactive EGFR can be found as a monomer on membrane level. Following ligand interaction EGFR will activate and form homodimers. Several ligands have been described: TGF-α, EGF, amphyregulin, heparin-binding EGF-like growth factor, betacellulin and epiregulin (9, 10).

EGFR may also interact with another ErbB family member such as ErbB2/Her2/neu forming an active heterodimer.

EGFR dimerization induces conformational changes thus increasing intrinsic intracellular tyrosine kinase activity. This results in multiple signal pathways activation; best known are: the RAS/RAF/MAPK pathway involved with cell proliferation, tumor invasion and metastasis, PI3K/AKT pathway leading to cell survival by inhibiting apoptosis thru nuclear transcription factors activation and the JAK/STAT

pathway similarly involved in transcription activation (11, 12).

Under normal conditions tyrosine kinase activity is balanced by tyrosine phosphatase; there are various mechanisms leading to tyrosine kinase dysfunctions – mutations are probably the most important. Extracellular domain mutations may induce ligand independent cell proliferation; such is the case for some glioblastomas, ovarian cancers and non small cell lung cancers. Point mutations of the extracellular domain have been described for myeloma and some somatic mutations were associated with cervix and bladder cancers (8, 13, 14).

The vast majority however involve the intracellular tyrosine domain; there have been no reports on transmembrane region mutations involved in ligand independent receptor activation.

Historically all advanced stage NSCLC patients were offered first line therapy – a combination of two agents (one being a platinum compound), docetaxel or permetrexed as second line therapy and erlotinib as a second or third line option.

The development of tyrosine kinase inhibitors (TKI) such as gefitinib and erlotinib has brought some minor survival improvements if whole NSCLC patient population was considered. Later research showed that some characteristics such as race (Asian), histology (adenocarcinoma), sex (female) and smoking status (non smoker) associate a greater response if EGFR TKI are used (7, 15, 16). This data lead the discovery of EGFR activating mutations which are predictive for response to TKI.

Mutation status can be assessed by either direct sequencing or targeted approaches.

Sequencing techniques have the main advantage to identify any mutation (previously known or not); their main drawback is the less sensitivity – samples with tumoral content over 20% are required and the method is work intensive including a PCR amplification stage prior to sequencing(1).

Targeted approaches are mainly used to detect a limited number of high clinical significance mutations – usually therapy response predictors. Sensitivity is higher and are reliably used for small biopsy or cytology samples (with down to 1% tumoral cell content).

All EGFR activating mutations were found on exon 18-21(3). Three mutation classes have been described: class I – exon 19 deletions almost exclusively involving the 747 – 749 aminoacid sequence accounting for around 44% of total EGFR mutations. Class II contains point mutations leading to aminoacid substitutions. Most frequent point mutation involves exon 21 (codon 858) leading to arginine>leucine substitution and accounts for 41% of activating TK changes. Less frequent (around 2%) class II mutations involves exon 18 - the 719 glicine is replaced by serine, alanine or cysteine (G719X) and L861Q for exon 21. Class III mutations are exon 20 duplicates or inserts and account for around 5% of total EGFR mutations (15).

To sum up, exon 19 deletions and exon 21 point mutations account for 90% of total activating EGFR mutations and are dubbed „classic" activating mutations. Their activating effect is achieved by ligand independent tyrosine kinase domain conformational changes. Exon 20 inserts associate with primary TKI resistance and T790M point mutation with secondary resistance. Activating mutations positive status is the best response predictor for TKI therapy;

recent data showed gene amplification and/or hyperexpression alone not to be effective independent predictors. Thus EGFR sequencing is the best approach to predict TKI response and progression free survival (1).

Some pharmacological agents have been developed to block different signaling pathways; almost every single one belong to the tyrosine kinase inhibitor group and EGFR targeted agents are included to every day practice (17-19).

MATERIAL AND METHOD

Retrospective study including IRO Iasi non-small cell lung cancer patients which underwent molecular investigations starting November 2013 untill September 2014.

Main aim was to retrospectively evaluate the EGFR mutations prevalence in non-small cell lung cancer in IRO Iasi patients during November 2013 – September 2014.

Surgical, endobronchial or minimally invasive transthoracic biopsy samples were collected from primary tumors and secondary sites (cerebral, pleural, lymphatic).

Sample processing

Samples were formalin fixed and paraffin embedded; tissue blocks were microtomed to 3-5 μm sections. Diagnosis was reached using classical stains and immunhistochemistry approaches (TTF-1, p63, CK7, CK5/6 were the most frequently used markers).

DNA extraction

The pathologist marked the high tumoral cell percentage regions on hematoxylin eosin stained 3 μm sections – then manual macrodissection on relevant 10 μm sections was performed to reduce non malignant cell content. Paraffin was removed (toluene 5 min, ethanol 3 min, ethanol 2 min) and DNA extraction was performed using Machery-Nagel "NucleoSpin FFPE DNAkit" and then amplified on a Applied Biosystem 7500 Real Time PCR System. The DNA quality (A260/280) and quantity (ng/μl) was evaluated by UV spectrofotometric method on a Eppendorf BiophotometerPlus and a HellmaTrayCell-Light path 1mm and a second measure was performed by fluorimetric method on a Qubit® 2.0 Fluorometer with the Qubit® dsDNA HS Assay Kit. The method that we used for the detection of EGFR mutations requires a 5-10 ng of genomic DNA per reaction (40-90 ng for a sample), with a limit of detection between 0,1-1% diluted in the wild-type genomic DNA. EGFR mutation status (positive, negative, undetermined) was assessed on Entrogen mutation EGFR kit using 10 ng of DNA extracted from paraffin embedded samples (surgical or endobronchial biopsies).

Demographic/clinical data was also collected – age, smoking status

Each patient signed an informed consent form.

RESULTS

There were 63 adenocarcinoma samples (17 females, mean age 60,9+/-9 years): 49 primary lung tumors and 14 secondary lesions (brain, lymph nodes, pleural). There was insufficient bioptic material for three cases (5%). TTF1 status was determined for 46 patients – forty were positive, 6 were negative and 17 had no data provided.

There were twelve mutations identified (7 female subjects, 5 male) - six L858R, five Del 19 and one G719X; ten were TTF1 positive for the remaining two TTF1 status was unknown. Female sex predominance was statistically significant (p=0.02, chi

squared).

Mean age for mutation positive patients was 64+/-10 years; there were three never smokers, three active smokers and no data on smoking status was available for six subjects.

DISCUSSION

Our data reveals 19.04% mutation positive; the majority are point mutations L858R and del19, there was only one G719X case.

From the six L858R cases 4 were females; exon 19 deletions were present for three females and 2 males, the G719X mutation patient was male.

There were more females among mutation positive patients but less than literature data; this may be interpreted as a selection bias and insufficient addressability.

Our study group was characterized by frequent exon 21 mutations (50% of total mutation positive); this may have practical implications given the fact that best TKI response is seen with exon 19 mutations (20). There is available data reporting on worse survival for exon 21 mutation patients as compared to exon 19 mutation subpopulation mainly treated with afaftinib but possibly also with first generation TKI (21, 22).

There are reports correlating TTF-1 expression and mutation status – EGFR mutations seem to be frequent in TTF-1 positive tumors (23, 24). Our data is similar as mutations were found almost exclusively in TTF-1 positive tumors. Published data suggests different mutation incidence – Asians associates greater mutation frequency (35-40%) as compared to Caucasians (11-13%) while black ancestry falls between (25, 26). Smoking status associations could not be assessed because history data was not always available or reliable.

EGFR mutations were identified for 12 out of 63 tested patients; to our knowledge this is the first Romanian study of this type up to date.

CONCLUSION

Although small dimension of the study group precludes statistical significance EGFR mutations seem to correlate with TTF1 status. More data from large patient numbers is necessary to profile EGFR mutation spectrum in local population. Limited data available seems similar to literature data. Local standard of practice could probably benefit from more intensive testing.

LEFT VERTEBRAL ARTERY HYPOPLASIA IN A TEENAGER WITH VERTIGO AND HYPOTENSION (Abstract): The vertebral arteries (VA) as a part of the vertebrobasilar cerebral circulation are one of the main branches of the subclavian artery. They have a diameter that varies from 1.5 to 5.0 mm. Congenital vertebral artery (VA) hypoplasia is an uncommon embryonic variation of posterior circulation with a frequency reported to be 2-6% from autopsy and angiograms. Vertigo is an illusion of movement, often horizontal and rotatory. In this article we present the case of a teenager diagnosed with left vertebral artery hypoplasia after episodes of headache, vertigo, drop attack and hypotension. **Keywords**: VERTEBRAL ARTERY, HYPOPLASIA, VERTIGO, DROP-ATTACK.

Vertebral artery hypoplasia was first described in the 19th century. Congenital hypoplasia of vertebral arteries is an uncommon embryonic variation of posterior circulation with a frequency of 2-6%, reported from autopsy and angiograms. It is classified as a vessel with a diameter in the entire course of less than 2mm to 3mm, or with a side difference equal or greater than 1:1.7 (1, 2).

This congenital variation can lead to cerebral hypo perfusion in the vertebrobasilar system supporting the brainstem and the occipital lobes a condition known as vertebrobasilar insufficiency (VBI). Common symptoms of VBI include: loss of vision in one or both eyes, double vision, dizziness (vertigo), numbness or tingling in the hands or feet, nausea and vomiting, slurred speech, changes in mental status, including confusion, loss of balance and coordination difficulty swallowing, generalized weakness in a part of the body (drop attack) (3,4).

Rapid unilateral injury to either peripheral or central vestibular structures produces the acute vestibular syndrome, which consists of severe vertigo, nausea and vomiting, spontaneous nystagmus, and postural instability (5).

It is important to differentiate a peripheral vestibular syndrome from a central one as the central vestibular disorders are caused often by an acute stroke that can rapidly lead to death.

We present the case of a teenager, who

was diagnosed with left vertebral artery hypoplasia after recurrent episodes of vertigo, headache and an episode of drop-attack.

CASE PRESENTATION

A 15 year old male teenager was admitted to our department, at the end of January 2015 for morning headaches, dizziness and chest pain. The patient is non-smoker, without any significant family or personal pathologic history.

Physical examination showed pale skin and mucosa, normal state of nutrition (BMI 21.8 kg/m^2), rhythmic heart sounds, with a hearth rate of 88/min, arterial blood pressure 90/65 mmHg. Clinical examination did not reveal any tenderness of the abdomen, the liver and spleen were not palpable, he had no signs of meningitis.

Laboratory tests at admission showed hypocalcemia and mild iron deficiency.

The electrocardiogram (ECG) revealed normal sinus rhythm (74/min), tall symmetric T waves in all derivation. The ECG Holter and ABPM have no pathological changes.

The echocardiography highlights grade II-III mitral regurgitation and level II tricuspid regurgitation.

Ophthalmologic, neurological, psychiatric consultations and electroencephalography were normal.

He was released with recommendations of symptomatics.

Subsequently, in March 2015 the patient is re-admitted for the evaluation of a physical asthenia (drop-attack episode) after exercise and psychic exertion. Clinical exam, ECG and neurological consult were again normal.

Given the echocardiography findings, the drop-attack episode and the persistent headaches, we performed a contrast MRI that revealed a threadlike vertebral artery (hypoplasia) with no other changes (fig.1, fig. 2).

Throughout the hospitalization he received treatment with Betaserc 24 mg twice per day and Tanakan 40 mg, 3 tablets per day with positive outcome. He was released with the recomandations to continue the treatment for 5 and 3 months respectively.

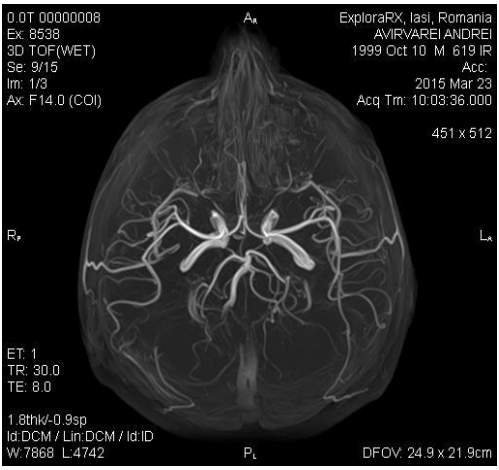

Fig. 1. Left vertebral artery hypoplasia – axial incidence

DISCUSSION

Vertigo is not a single disease entity but the cardinal symptom of different diseases of varying etiology; these may arise from the inner ear, brainstem, or cerebellum or may be of psychic origin (6).

Disequilibrium, which occurs when the brain receives inadequate information about the body's position from the somatosensory, visual, and vestibular systems, may result from peripheral neuropathy, eye disease, or peripheral vestibular disorders (7). Ménière's syndrome appears to be the final common pathway of the mechanisms the inner ear responds to almost any injury (8).

Functional disturbances of the optic nerve generate general physical and pathological reactions and some spontaneous remissions of immediate blindness can be explained. Secondary appearance of impairments or blindness can be explained by brain hematomas, edemas, nervous system disorders (9).

Presyncope is caused by cardiovascular disorders reducing cerebral perfusion (7).

Our patient, a teenager of 15 years, had no prior cardiac or neurological disease but had symptoms of headache, vertigo, chest pain and an episode of drop-attack that can suggest a cardiac cause.

However the physical exam, laboratory and paraclinic explorations found a cerebrovascular cause, more specific a left vertebral artery hypoplasia.

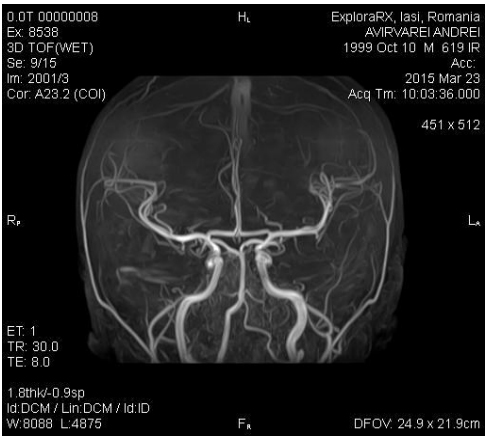

Fig. 2. Left vertebral artery hypoplasia – coronary incidence

Congenital anatomical variations of both vertebral arteries are relatively frequent; left vertebral artery dominance presents in 50% of the population, while similar size vertebral arteries present with an only 25% prevalence (10).

Therefore, because of this high prevalence, hypoplasia of vertebral artery alone is not considered a risk factor for stroke as it is a common variant in up to 75% of the general population (11).

However recent case reports and cohort studies suggest that its occurrence should not be negligible, mostly if it coexists with known risk factors of stroke (age>65, african-american race, female gender, family history and prior stroke, AIT or hearth attack, high blood pressure, cigarette smoking, diabetes mellitus, cardiovascular disease, high blood cholesterol, obesity and physical inactivity) that may increase the negative clinical impact (1, 2, 10, 11, 12).

CONCLUSIONS

Our patient was discovered with mitral and tricuspid regurgitation that are mostly mild and no restrictions or therapy is needed but in time it may lead to complications as abnormal heart rhythms, infections of the heart valve or heart failure. This is why we need to raise awareness on the fact that in a young patient with vertebral artery hypoplasia, without any important risk factor for stroke or cardiac disease, attention should be still high for controlling them and getting a positive outcome.

NEWS

THE IMPORTANCE OF MOLECULAR BIOLOGY TESTS IN THE DIAGNOSIS OF *CLOSTRIDIUM DIFFICILE* INFECTION

C. difficile is an anaerobic bacterium that causes pseudomembranous colitis after antibiotic therapy. Between 3% and 7% of healthy people are colonized with *C. difficile*, but the percentage increases among people hospitalized. *C. difficile* infection diagnosis is based on clinical manifestation and is confirmed by the immunoassay test for *C. difficile* toxins and PCR for bacterial DNA. A recent study showed that the exclusive use of PCR in the diagnosis of *C. difficile* infection without immunological tests for toxins may conduct to over diagnosis and overtreatment. The duration of diarrhea during treatment, rate of complications and mortality rate for patients Tox−/PCR+ were comparable to patients without *C. difficile* (Tox−/PCR−) and lower than Tox+/PCR+ patients. These findings suggest that the treatment is not necessary for patients who were positive by PCR testing but negative by toxin immunoassay (Polage CR, Gyorke CE, Kennedy MA, Leslie JL, Chin DL, Wang S, Nguyen HH, Huang B, Tang YW, Lee LW, Kim K, Taylor S, Romano PS, Panacek EA, Goodell PB, Solnick JV, Cohen SH. Overdiagnosis of *Clostridium difficile* infection in the molecular test era. *JAMA Intern Med*. 2015. doi:10.1001/jamainternmed.2015.4114).

PSYCHOMETRIC HEPATIC ENCEPHALOPATHY SCORES FOR THE DIAGNOSIS OF MINIMAL HEPATIC ENCEPHALOPATHY IN ROMANIAN CIRRHOTIC PATIENTS - PARTIAL RESULTS (Abstract): In Romania, minimal hepatic encephalopathy (MHE) is underdiagnosed and undertreated in patients with liver cirrhosis. The psychometric hepatic encephalopathy score (PHES) is recommended as the first-line tool for the diagnosis of MHE. **Aim:** To use PHES in a group of Romanian cirrhotic patients and highlight the relationships between demographic and biological factors and tests results. **Materials and Methods:** Of the 148 patients with liver cirrhosis admitted to the Iaşi Institute of Gastroenterology and Hepatology between August 2014 and February 2015 only 80 who met the eligibility criteria were enrolled and completed the study. Blood samples for routine tests and serum ammonia were collected from all patients on the day of PHES evaluation. **Results:** In the study group (n = 80) mean age was 57.7 ± 8.5 years, and the average number of years of education was 11.2 ± 2.7. The main causes of cirrhosis were alcohol consumption (31 patients - 38.8%), hepatitis C virus infection (29 patients - 36.3%) and hepatitis B virus infection (17 patients - 21.3%). Age, number of years of education, severity of liver disease (measured by using Child-Pugh and MELD scores) and some biological constants (albumin, bilirubin, International Normalized Ratio- INR) were significantly correlated ($p < 0.05$) with most psychometric tests. **Conclusions**: PHES is a practical, objective and useful method for the diagnosis of MHE. Demographic and biological factors correlated with the results of the psychometric test. The PHES requires standardization before applying it in Romanian cirrhotic patients. **Keywords:** MINIMAL HEPATIC ENCEPHALOPATHY, PSYCHOMETRIC HEPATIC ENCEPHALOPATHY SCORE, LIVER CIRRHOSIS.

Minimal hepatic encephalopathy (MHE) is a brain dysfunction caused by liver insufficiency and/or portosystemic shunting; patients with MHE have a normal neurological and mental status on physical examination but neurocognitive deficits detectable by neuropsychometric or neurophysiological tests (1). MHE has a negative impact on quality of life, daily activities (reading, driving, social interactions, decreased work performance) and is associated with a high risk for progression to overt hepatic encephalopathy (OHE) (2). The diagnosis of MHE is necessary in cirrhotic patients who are at

increased risk for work and automobile accidents, have subjective complaints, or report a decline in work performance (3). Several neurophysiological and neuropsychological tests are used to diagnose MHE, but most of them are expensive and require sophisticated equipment and highly trained personnel (4). According to the recommendations of the International Society for the Study of Hepatic Encephalopathy and Nitrogen Metabolism (ISHEN), the psychometric hepatic encephalopathy score (PHES) is the first-line option in the diagnosis of MHE (5). PHES consists of 5 paper-pencil tests performed at the bedside and involves minimal costs: digit-symbol test (DST), number connection test A and B (NCT-A, NCT-B), serial dotting test (SDT) and line drawing test (LDT) (6). According to previous studies, test results can be influenced by multiple factors (age, occupation, education) and the resulting nomograms differ depending on the tested population (7-11). In this study our objectives were: i) use of PHES in a group of Romanian cirrhotic patients; ii) correlations between demographic and biological factors and psychometric test results.

MATERIAL AND METHODS

148 patients with liver cirrhosis were included in the study. The diagnosis of liver cirrhosis was based on clinical, biological, imaging (ultrasound, endoscopy, and computed tomography) or anatomopathological criteria (liver biopsy). Patients were admitted to the Institute of Gastroenterology and Hepatology – Iasi "St. Spiridon" Hospital between August 1, 2014 and February 28, 2015. After applying the following exclusion criteria, 80 (54%) patients were enrolled and completed the study (7.9):

- OHE (diagnosed according to West Heaven criteria) – at current admission/history;
- Diagnosis of hepatocarcinoma /other malignancies;
- Use of psychotropic drugs or neuropsychiatric disorders (dementia, epilepsy, ethanol withdrawal);
- Use of lactulose and/ or antibiotics;
- Active ethanol consumption ($\geq$ 50 g/day in men and $\geq$ 30 g/day in women);
- Chronic kidney, lung or heart diseases;
- Visual disturbances not corrected by glasses.

On the day of the psychometric tests blood samples were collected for routine tests and venous ammonia. Liver function was assessed by calculating the Child-Pugh and MELD (Model for End Stage Liver Disease) scores. Subjects included in the study were interviewed about education, occupational status, alcohol consumption, knowledge of Romanian alphabet and numbers. After a preliminary demonstration, all patients completed the 5 tests that make up PHES (DST, NCT-A, NCT-B, SDT, LTT) as instructed by the physician investigator. The results of DST test were measured as points and those of NCT-A, NCT-B and SDT tests as seconds. The results of the LTT were measured as both the time needed to complete the test (LTTt, seconds) and as the error score (LTTe). Tests were conducted between 10 am and 3 pm (in a well-lit, quiet room), being supervised and interpreted by a single investigator. PHES forms and the directions for administration were made available to our team by the courtesy of Prof. Dr. Karin Wissenborn (Hannover - Germany).

Written informed consent was obtained from all patients. The study protocol conformed to the ethical guidelines of the 1975 Declaration of Helsinki, and was approved by the ethics committees of the Iasi "Grigo-

re T. Popa" University of Medicine and Pharmacy and "St. Spiridon" Hospital.

For statistical analysis the Statistical Package for Social Sciences (SPSS version 19.0, Chicago, IL, USA) was used. Quantitative data were expressed as means ± standard deviation or as number of subjects percentages (n, %). To measure the relationship between two variables the Pearson correlation coefficients were used. A *p* value of less then 0.05 was considered statistically significant.

RESULTS

For the patients enrolled in the study (n = 80) mean age was 57.7 ± 8.5 years, and the average number of education years was 11.2 ± 2.7. Distribution of patients by sex, age and years of education is shown in fig. 1 (A and B).

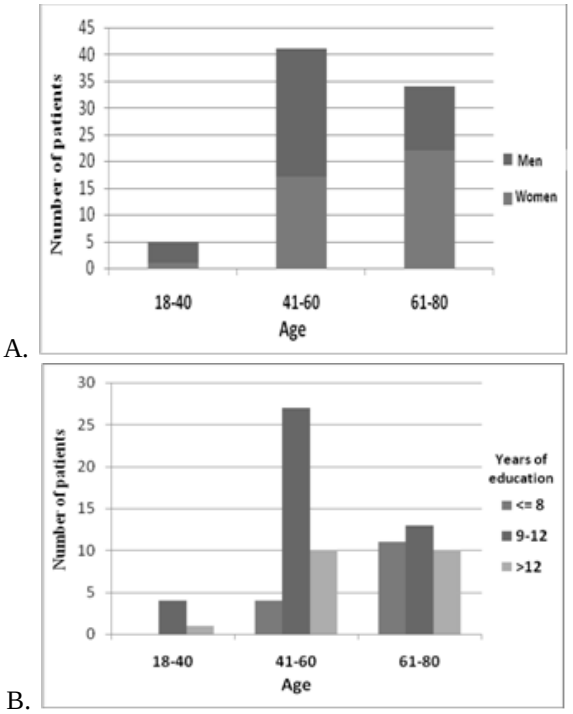

Fig. 1. Distribution of patients by sex, age and years of education

The main cause of liver disease was alcohol consumption - 31 (38.8%) patients, followed by hepatitis C virus infection - 29 (36.3%), hepatitis B virus infection - 17 (21.3%) and autoimmune diseases - 3 (3.6%). Distribution of patients according to Child-Pugh classification was as follows: Class A - 38 (47.5%) patients, class B - 32 (40%), class C - 10 (12.5%). The complex demographic data, biological parameters, causes and severity of liver disease (Child-Pugh and MELD scores) are shown in tab. I.

The results of DST, NCT-A, NCT-B, SDT, LTT-t LTT-e tests (mean ± SD) were: 30.1 ± 9.3 points, 57.4 ± 24.8 s, 149.6 ± 56.3 s, 71.7 ± 15.1 s, 105.3 ± 33.6 s and 47.6 ± 29.5 points, respectively. Age, number of years of education and severity of

liver disease (measured by Child-Pugh and MELD scores) were significantly correlated ($p < 0.05$) with the results of the majority of psychometric tests. Alcohol consumption, environment (rural/urban), gender (male/female) did not influence the final results (tab. II).

The following serum biological parameters correlated statistically significant ($p < 0.05$) with most of psychometric tests: INR (International Normalized Ratio), serum albumin and bilirubin (tab. III).

TABLE I

Demographic and biochemical data of patients with liver cirrhosis;

Demographic and biochemical data	*Patients with cirrhosis (n=80)*
Age (years, mean ± SD)	57.7±8.5
Sex (male/female)	40 (50%)/40(50%)
Education (years, mean ± SD)	11.2 ±2.7
Ethanol consumption (YES/NO)	22(27.5%)/58(72.5%)
Environment (rural/urban)	39 (48.8%)/41(51.2%)
Etiology of cirrhosis	
Toxic	31(38.8%)
Hepatitis B virus	17(21.3%)
Hepatitis C virus	29(36.3%)
Autoimmune	3 (3.6%)
Child-Pugh class	
A	38 (47.5%)
B	32 (40%)
C	10 (12.5%)
MELD score (mean ± SD)	11.8±4.6
Na (mEq/l,mean ± SD)	137.1 ± 3.5
K (mEq/l, mean ± SD)	4.2 ± 0.6
Creatinine (mg/dl, mean ± SD)	0.8 ± 0.3
INR (mean ± SD)	1.2 ± 0.3
Albumin (g/l, mean ± SD)	3.7 ± 0.7
Bilirubin (mg/dl, mean ± SD)	2.3 ± 2.3
Venous ammonia (µg/dl, mean ± SD)	81.8 ± 34.6

DISCUSSION

PHES is a useful tool for the diagnosis of minimal hepatic encephalopathy and for the study of neuropsychological disorders associated to this pathology (visual-spatial orientation, psychomotor speed, visual perception, attention, concentration and working speed) (12). Psychometric tests were initially studied by Schomerus et al. and standardized by Weissenborn et al. in the German population (6). The tests were later adopted and validated in other countries - Spain, Italy, Mexico, India, Korea and Poland (7-11).

Our study presents the partial results of the PHES standardization for the diagnosis of MHE in Romanian cirrhotic patients. PHES was applied to 80 patients diagnosed with cirrhosis, equally distributed by gender, from both rural and urban areas. In agreement with data in the literature (7-11) in our group of patients the severity of liver disease (Child-Pugh and MELD scores), demographic factors (age and years of education) and biological parameters (bilirubin, INR, albumin) correlated with the results of psychometric tests. In our study, sex, alcohol consumption and environment (rural/urban) did not influence the final results of the tests, the data being consistent with studies conducted in Italy or Spain (10, 11).

Some studies for PHES standardization, such as those in Poland and Korea, showed a statistically significant correlation between ammonia and psychometric tests (7.9). In our study patients ammonia level did not affect the test results, possibly because we used venous and not arterial blood sampling. The statistically significant correlations between Child-Pugh and MELD scores found in our study have been also reported by other studies (7 to 9,11).

In our group of patients with liver cirrhosis we have demonstrated a significant association between biological parameters (serum albumin, INR, serum bilirubin) and most of the psychometric tests. In the Polish study PHES correlated with serum albumin, while in the Korean study there were no statistically significant associations between serum parameters and neuropsychological tests (7, 9).

The significant correlations between psychometric tests and demographic factors certify the need for PHES standardization in the respective country population prior to its use for the diagnosis of MHE. The use of psychometric tests in a sample of healthy individuals and subsequently the provision of norm data represents the next step for the validation of PHES in the Romanian population.

CONCLUSIONS

PHES is a useful, objective, inexpensive and simple method for the diagnosis of MHE in patients with liver cirrhosis. In our study, psychometric tests correlated with the severity of liver disease (Child-Pugh and MELD scores), demographic factors (age and years of education) and serum parameters (bilirubin, INR, albumin). In order to apply the PHES to Romanian patients, the psychometric tests require standardization based on specific demographic factors (age and years of education).

DIAGNOSTIC AND PROGNOSTIC VALUE OF PRESEPSIN IN THE EMERGENCY DEPARTMENT (Abstract): Sepsis syndrome is a common situation and has devastating implications on health care systems worldwide. Biomarkers may have an important role to highlight the presence, absence or severity of sepsis. **Material and methods**: Retrospective study is conducted on a group of 95 suspected sepsis patient (0.16%) out of a total of 56,996 patients that were presented in the Emergency Department / Emergency County Hospital "St. Spiridon" from Iaşi during 01.01.2012-01.12.2012. The study aims to establish the following: the incidence of sepsis diagnosis, analysis of prognostic factors, relationship between the presepsin value and clinical outcome. **Results**: In men, there was a distribution of cases between the age of 22 years up to 89 years with an average confidence interval between 59.32 and 67.23 years, and the distribution of cases varies among women from age of 40 years up to 93 years, with an average confidence interval between 65.53 and 75.47 years The most frequent primary source of infection is localized at the pulmonary level, in a total of 21.1%, followed by abdominal location occurring in a total 14.7%. Area under the curve in ROC curve analysis regarding mortality showed significant values of area for presepsin (0.859), leukocytes (0.790), traumatic injuries association (0.761) and the presence of gastrointestinal history. **Conclusions**: Presepsin has diagnostic value, early prognostic value and is an early marker of mortality in septic patients. Trauma associated with severe systemic infection leads to an increase in mortality. **Keywords**: SEPSIS, BIOMARKER, PRESEPSIN, MORTALITY.

The progress made over the last two centuries in fighting against infectious pathology may suggest at first glance an optimistic vision of this type of pathology compared to the early era of antibiotics. Sepsis is defined as an infectious disease, caused by bacterial microorganism, evolving as a serious systemic infection and will progress to severe sepsis (acute organ dysfunction caused by an infection or suspected to be caused by an infection) and to septic shock (severe sepsis associated with hypotension that does not respond to fluid resuscitation therapy), installed as a result of discharging in the blood flow of pathogens, toxins and cellular disintegration products. Sepsis and its clinical forms must be regarded as stages of the same disease (1).

Sepsis syndrome is a common in Intensive Care Units and has devastating implications on health care systems worldwide.

Estimated average annual cost for care of patients with sepsis was calculated to be worth $ 16.7 billion in 2008 (2).

Severe systemic infection and sepsis are challenging overcrowded emergency services, and in literature is described various causes of severe *sepsis*, even after intrauterine devices insertion (3). Other issue is the fact that septic infections were characterized by etiologic polymorphism and resistance to antibiotics (4). Failure to recognize these entities at the appropriate time, followed by early initiation of therapy and supportive etiological treatment can lead to degradation of vital parameters or even death in these patients. Hence the need for the use of laboratory diagnostic methods easy to use with high sensitivity and specificity to allow an early diagnosis prior installation of septic shock phase.

Biomarkers may have an important role to highlight the presence, absence or severity of sepsis, and can differentiate a bacterial infection of viral or fungal, in addition helps the differential diagnosis of sepsis (systemic infection) with a local infection.

Presepsin (sCD14-ST) - CD 14, is a glycoprotein expressed on the cell membrane surface of monocytes and macrophages present in macrophages, monocytes and granulocytes, is responsible for intracellular signal transmission triggered by the presence of endotoxins. Soluble fraction was called soluble CD14 subtype or presepsin has increased plasma levels in infections.

Cut-off value of presepsin allowing systemic inflammatory response syndrome differentiation within bacterial infectious diseases and nonbacterial was determined to be 600 pg/ml, the clinical sensitivity and specificity were 87.8% and 81.4% (5).

MATERIAL AND METHODS

This study is a retrospective study conducted on a group of 95 (0.16%) patients with suspected sepsis out of a total of 56,996 patients that were presented in the Emergency Unit - Emergency County Hospital “St. Spiridon” from Iaşi during 01.01.2012 -01.12.2012.

The study aims to establish the following:

- Incidence of sepsis diagnosis presented in the Emergency Unit - Emergency County Hospital "St. Spiridon "- Iasi;
- Clinical-tracking according to the precocity of when the patients are diagnosed and how long the therapy is initiated;
- Analysis of prognostic factors;
- Analyzing the relationship between trauma and sepsis on survival;
- The relationship between the obtained presepsin value and clinical outcome (on early diagnosed and properly treated patients).

The study protocol included the following data taken from the group of patients: epidemiological, clinical and laboratory variables, medical treatment administered in the Emergency Department (ED) - Hospital “St. Spiridon” from Iaşi, evolution.

Inclusion criteria: patients over 18 years; patients with clinical signs of infection accompanied by the presence of at least two of the following criteria: temperature > 38°C or < 36°C, heart rate > 90 / min, respiratory rate > 20 /min and leukocytosis (>12,000 mm^3) or leukopenia (<4,000 mm^3).

Exclusion criteria: patients under age of 18 years; patients who are pregnant or lactating.

The diagnosis of sepsis was made based on the clinical signs (specific and usually signs) in conjunction with other investiga-

tions, respecting the diagnostic criteria from Surviving Sepsis Campaign statements (5).

For each patient with suspected sepsis in the ED, approach was standardized based on specific protocols existing on emergency medicine specialties. The patient was clinically evaluated, vital signs was monitored and when clinical suspicion of infection arise the clinicians started to complete a case sheets including clinical and laboratory variables listed according with the definition of sepsis.

For patients who experienced associated traumatic injuries, protocol was applied for diagnosis and treatment of trauma patients according to existing guidelines and protocols.

Data collected from records of patients meeting inclusion criteria were processed statistically using statistical analysis software IBM-*SPSS 22.0.*

RESULTS

Structurally, the study group included 61 men, corresponding to a percentage of 64.21% and 34 women, representing a rate of 35.79%. Statistical analysis highlights an average age of 65.86 years in study participants, the mean age being 63.28 on men and 70.5 years on women (tab. I).

TABLE I

Table comparision mean age male/female

Sex related distribution	Mean	N	Std. Deviation
Male	63.28	61	15.443
Female	70.50	34	14.254
Total	65.86	95	15.351

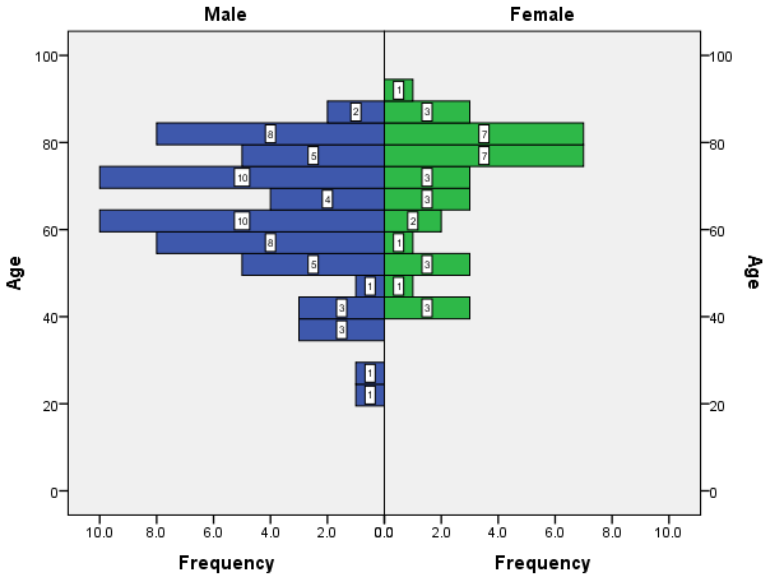

Fig. 1 Distribution of patients according to sex and age group

In men, there was a distribution of cases between the age of 22 years up to 89 years with a average confidence interval between 59.32 and 67.23 years, and for women the distribution of cases varies by age in a range from 40 years up to 93 years, with an average confidence interval between 65.53 and 75.47 years. The highest frequency recorded in men's was in 60-80 years age range and for women the most frequent cases were recorded in the range 70-80 years (fig. 1).

The most frequent primary source of infection is localized in the lung, 21.1%, followed by abdominal location occurring in 14.7%. In a percentage of 45.3% we could not detect during their presence in the E. D."St.Spiridon" the primary source of infection (tab. II).

TABLE.II

Primary source of infection

Primary source		Frequency	Percent	Valid percent	Total percent
Territory	Unspecified	43	45.3	45.3	45.3
	Pulmonary	20	21.1	21.1	66.3
	Cutanat	7	7.4	7.4	73.7
	Genito-Urinary	7	7.4	7.4	81.1
	Abdominal	14	14.7	14.7	95.8
	Central Nervous System	3	3.2	3.2	98.9
	Cardiac	1	1.1	1.1	100.0

The distribution of the starting point of systemic infection coupled with a mean age of patients shows a high average age for starting point located on pulmonary territory (71.5 years), followed by abdominal starting point (70.64 years), with the lowest average age if systemic infection was with cardiac starting point (22 years) (tab.III).

TABLE III

Epidemiological characteristics by age and primary source of infection

Diagnostic	Mean	N	Std. Deviation	Range	Minimum	Maximum
Unspecified	65.26	43	14.825	68	25	93
Pulmonary	71.50	20	13.690	51	38	89
Cutaneous	59.71	7	14.557	39	40	79
Genito-Urinary	61.86	7	13.434	33	51	84
Abdominal	70.64	14	13.765	45	44	89
Central Nervous System	53.00	3	19.672	39	35	74
Cardiac	22.00	1	.	0	22	22
Total	65.86	95	15.351	71	22	93

In addition to the usual biological constants laboratory determining, presepsin values determination was made in all patients included in the study, we observed an average value of its 2,519.25 pg / ml (tab. IV).

TABLE IV
Biological variables values

	N	Minimum	Maximum	Mean	Std. Deviation
Leucocytes	95	880	66,100	17,778.42	11,012.784
Thrombocytes	95	52,900	60,2000	253,029.47	133,950.395
INR	95	0	2	0.54	0.727
Glycemia	95	46	460	155.55	77.027
pH	95	6.80	7.58	7.3501	0.17002
RA	95	4.9	39.0	21.088	6.9188
Presepsin	95	145	20000	2519.25	3,169.939

We analyzed using Receiver Operating Characteristic curve (ROC) the correlation between the presepsin value and mortality in the group of patients, along with other variables but statistical significance values were obtained only between the value of leukocytes, history of gastrointestinal disease and trauma association in patients with sepsis (tab.V, fig.2). Area under the curve (AUC) showed significant values for presepsin (AUC=0.859), leukocytes (AUC=0,790), traumatic injuries association (AUC=0.761) and the presence of gastrointestinal history.

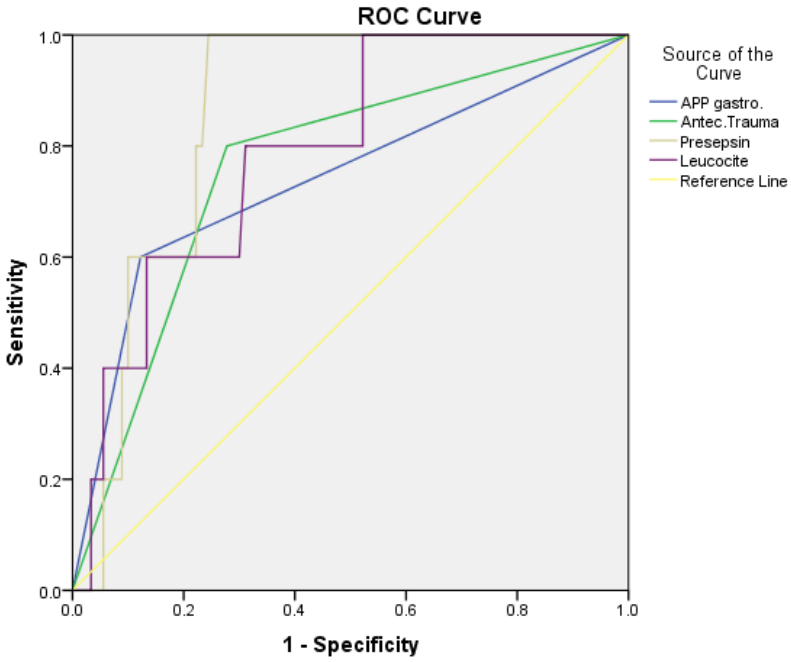

Fig. 2 ROC curve mortality-presepsin, leucocytes, trauma, and history of gastrointestinal disease

TABLE V

ROC Curve Mortality

Test Result Variable(s)	Area	Std. Error[a]	Asymptotic Sig.[b]	Asymptotic 95% Confidence Interval	
				Lower Bound	Upper Bound
Gastro-intestinal history	.739	.134	.073	.477	1.000
Trauma history	.761	.108	.050	.550	.973
Presepsin	.859	.046	.007	.769	.949
Leucocytes	.790	.087	.030	.619	.961

The analysis of correlations between variables was made using Pearson method, significant correlations were detected between traumatic injuries and need for orotracheal intubation maneuver, mortality, low Glasgow coma score (GCS less than 9 points) and admission on intensive care unit. The analysis of presepsin show statistically significant correlations between this values and the presence of septic shock, need for vasopressor medication and need for advanced management on airways orotracheal intubation (OTI) (tab. VI, VII, VIII).

DISCUSSION

The sepsis average age described in the literature has increased over time, from an average of 68.2 years up to 64.1 years, the average age obtained in the present study were of 65.86 years (7). Men have more susceptibility than women to develop sepsis and severe sepsis, the data of the present study is consistent with international reporting (8).

Most commonly the initial source of infection that developed sepsis is described in the literature to be on pulmonary level, followed by 2nd primary location on gastrointestinal level, the values obtained by us located the same frequency in the top, and also in literature a significant proportion of sepsis cases described the primary infection location as uncertain or not identified (8, 9).

Presepsin is described as the only independent variable that can be associated with survival at 28 days or hospitalization in the intensive care ward and prognostic accuracy is increased compared with procalcitonin and other biomarkers (10, 11, 12). The area under the curve obtained in our study show values comparable to those described in the few studies published up to present date, the value obtained in this study were AUC=0.859, compared with other studies that showed values between AUC=0.640 to AUC= 0.790 (11, 12).

The correlation between the occurrence of septic shock, presepsin value and need for vasopressor therapy was recently described in the literature (13).

The combination of traumatic injuries and further development of sepsis and severe sepsis is described in the literature, with a predominance of this pathology in males, with a mortality still high, ranging from 19.5-23% of cases (14, 15) . Due to the increased severity of this association is explained correlation with the need for advanced airway management and low Glasgow coma score on this category of patients.

CONCLUSIONS

Presepsin early diagnostic value may also have prognostic value over the subsequent evolution of the patient.

Presepsin is an early marker of mortality in septic patients.

Trauma associated with severe systemic infection leads to an increase in mortality compared with patients in the group that did not have a diagnosis of trauma associated (p=0.013).

Endotracheal intubation maneuver needs to be considered in patients with the diagnosis of sepsis associated with trauma (p=0.00076).

Combination of multiple trauma injury and sepsis will lead to a fast deterioration in neurological status of the patient, the Glasgow coma score fell below 9 points in these patients (p = 0.014).

NEWS

INTERACTION BETWEEN EBOLA VIRUS AND THE EXTRACELLULAR MATRIX

Ebola virus disease (EVD) represents a global public health threat concern. Limited therapeutic and prophylactic options are available for patients suffering from this disease. The EV glycoprotein (GP) is the main determinant causing structural damage of endothelial cells which triggers the hemorrhagic diathesis. However, the molecular mechanisms of this phenomenon remains elusive. In a study by Veljkovic et al. the interaction of GP with endothelial extracellular matrix (ECM) was investigated using the informational spectrum method (ISM), a virtual spectroscopy method for analysis of the protein-protein interactions. The results of the study suggest that Elastin Microfibril Interface Located Proteins (EMILINs) are involved in interaction between GP and ECM. The study concluded that this finding leads to a better understanding of EV/endothelium interaction and its role in pathogenesis, prevention and therapy of EVD (Veljkovic V1, Glisic S1, Muller CP2, Scotch M3, Branch DR4, Perovic VR1, et al. In silico analysis suggests interaction between Ebola virus and the extracellular matrix. Front Microbiol. 2015; 6: 135. doi: 10.3389/fmicb.2015.00135. eCollection 2015).

PARTICULARITIES OF THE ETIOLOGY OF HYPONATEREMIA IN THE FRAIL ELDERLY PATIENT

PARTICULARITIES OF THE ETIOLOGY OF HYPONATEREMIA IN THE FRAIL ELEDERLY PATIENT (Abstract). Hyponatremia is the most common electrolyte disorder in medical practice, and its prevalence is increasing in frail elderly patients. There are many reasons behind this phenomenon: the changes induced by aging itself, the presence of comorbidities and polypharmacy, the increased risk of dehydration, increased frequency of iatrogenesis and therapeutic noncompliance. Of the iatrogenic causes, we will refer to hyponatremia induced by thiazide-type and thiazide-like diuretics (1) due to 4-fold increase in prevalence in the frail elderly patients. Hyponatremia is a disease that benefits from prompt and appropriate treatment with excellent results, but the key to therapeutic success is the determination of its cause - which can be difficult in the elderly, and of patient's volume status for a correct classification of the disease. Hyponatremia in frail elderly patients may be asymptomatic or mimic other diseases. These are due to the almost constant association of varying degrees of geriatric syndromes, the most often responsible for symptom mystification being the cognitive impairment, the presence of comorbidities that have similar symptoms, the overlapping of acute events - fractures resulting from same-level falls that distort the diagnosis. We report 3 cases of hyponatremia characterized by atypical symptoms that was induced by indapamide treatment. Hospitalization for thiazide-induced hyponatremia is frequent, suggesting suboptimal monitoring, especially during the treatment initiation phase. Literature data suggest that the ionogram should be obtained 7 to 14 days after treatment initiation to detect the early onset of hyponatremia. There are reports of hyponatremia occurring after years of treatment, suggesting the need for constant monitoring of a patient treated with long-acting thiazide diuretics. Considering an iatrogenic cause (most commonly induced by thiazide-type or thiazide-like diuretics) should be in the forefront of physician's mind, but it requires a thorough medical history, assessment of patient compliance and cognitive status as well as support from patient's family. Identification of the cause of hyponatremia should prevent recurrences and provide adequate patient education to prevent secondary complications. **Keywords**: HYPONATREMIA, FRAIL ELDERLY PATIENTS, INDAPAMIDE TREATMENT.

Hyponatremia is the most common electrolyte disorder in medical practice, and its prevalence is even greater in frail elderly patients due to the addition of some particularities of this age segment: changes induced by aging per se, presence of comorbidities and polypharmacy, increased risk of dehydration (both by a natural predisposition to low daily fluid intake of the elderly and by the existence of such conditions that favor dehydration as prolonged and repeated hospitalizations, perioperative hydrological

restrictions), increased frequency of iatrogenesis and therapeutic noncompliance. Among the iatrogenic causes, we draw attention to hyponatremia induced by thiazide-type and thiazide-like diuretics (1) due to the up to 4-fold increase in prevalence in the frail elderly patient (2). Most elderly patients have varying degrees of hyponatremia. The severe form (Na < 125 mmol/l) is usually characterized by obvious clinical symptoms: altered general state, marked physical asthenia, seizures, nausea and vomiting culminating with the severe forms: hyponatremic encephalopathy, noncardiogenic pulmonary edema, coma and death (3). Moderate forms of hyponatremia have more attenuated and polymorphic symptoms, and in frail elderly patients they may be asymptomatic or mimic other pathologies. These are due to the almost constant association of varying degrees of geriatric syndromes, the most frequently responsible for symptom mystification being cognitive impairment, the presence of comorbidities with similar symptoms, the overlapping of acute events - fractures resulting from same-level falls that distort the diagnosis (3.4). Hyponatremia is a disorder that benefits from prompt and appropriate treatment (1), but the key to therapeutic success is the determination of its cause - which can be difficult in the elderly, and of patient's volume status for a correct classification of the disease.

To exemplify, we report three cases with various forms of hyponatremia who shared the advanced age, presence of comorbidities and polymedication, the common element being the treatment with thiazide-like diuretic (indapamide).

CASE REPORTS

Case 1: a 68-year-old woman with polymedication due to polypathology: digestive (gastroesophageal reflux disease, chronic gastritis and hepatitis C for 11 years treated with 3 different drugs) and cardiovascular (AHT and heart failure for which she received a 10-day treatment with 4 different drugs - a fixed combination of perindopril 10 mg and indapamide 2.5 mg, trimetazidine, platelet antiaggregant and statin). Five days before the doctor's appointment, the patient became symptomatic, presenting vertigo, headache, nausea and vomiting, and presented to the Gastroenterology department. Routine biological screening revealed severe hyponatremia (Na = 121 mmol/L) and hypokalemia (K = 3.28 mmol/L). A digestive cause was ruled out and she was referred to the Geriatrics Clinic. The thorough history confirmed the compliance with treatment and low-salt diet and a normal neurocognitive status (MMSE = 29/30). The volume status was assessed using echocardiography, which revealed normal diameter and almost complete inspiratory collapse of the inferior vena cava, suggestive of a diagnosis of iatrogenic euvolemic hyponatremia (indapamide). Slow correction of ionic imbalance was initiated by the discontinuation of the thiazide-like diuretic and normal dietary salt intake followed by oral and parenteral hydration with isotonic saline for 8 days. The course was slowly favorable, with the remission of symptoms and correction of ionic imbalance, on discharge the Na level being within normal ranges (143 mmol/L).

Case 2: an 83-year-old male patient with difficult to take history and without medical documents, with cardiovascular and rheumatic polypathology (according to his daughter who also mentioned the home treatment with indapamide) and who had sustained a craniocerebral trauma from same-level fall, for which he was urgently investigated at the Neurosurgery department. Routine biological screening revealed

severe hyponatremia (Na = 118 mmol/L) and hypokalemia (K = 3.2 mmol/L) and he was referred to the Geriatrics Clinic. The assessment of volume, clinical and echocardiographic status oriented the diagnosis towards hypovolemic hyponatremia possibly of multiple etiology: iatrogenic (indapamide) and secondary to dehydration by insufficient fluid intake. Geriatric assessment revealed impaired neurocognitive status (MMSE = 19/30) and malnutrition risk. The conservative correction of hypovolemic hyponatremia was initiated by discontinuing the thiazide-like diuretic and replacing it with a non-dihydropyridine calcium blocker to control blood pressure levels. The patients received parenteral hydration for 5 days with 500 mL of isotonic serum enhanced with 20 mL micro perfusions of 5.85% NaCl with dynamic ionogram monitoring and slow correction of hyponatremia to prevent osmotic demyelination with serious neurological consequences (5). For the correction of hypokalemia, 10 mL intravenous KCI was added to the treatment schedule on admission day, followed by oral administration in doses adapted according to the ionogram.

Case 3: a 69-year-old female patient polymedicated and with polypathology (cardiovascular, receiving treatment with 5 different drugs/day, metabolic, insulin-dependent diabetes mellitus for which she was on treatment with 2 oral antidiabetic drugs and insulin, dyslipidemic syndrome and morbid obesity, and cerebral pathology for which she took 3 other drugs/day); the patient reported the onset of symptoms a few days earlier by progressively increased leg edema, dyspnea at increasingly smaller efforts, physical asthenia and vertigo, for which she presents to the Cardiology Department where, in addition to the existing diagnoses, altered renal function (Cl creatinine = 39 mL/min) and severe hyponatremia (Na = 124 mmol/l) were detected and the patient was referred to the Geriatrics Clinic. Clinical assessment (leg edema, moderate dyspnea) and echocardiography (slight inferior vena cava inspiratory collapse) suggest hypervolemic hyponatremia of multiple etiology, the main causes being the lack of therapeutic compliance (chaotic treatment, especially in case of indapamide) and diet with inadequate fluid intake (polydipsia). Geriatric evaluation revealed mild cognitive impairment (MMSE = 25/30) and depressed status (GDS = 8/15). Correction of electrolyte and volume disturbances was initiated: discontinuation of indapamide and replacing it with intravenous furosemide, water restriction (500 mL/day), correction of diabetes. The course was slowly favorable at the same time with the correction of hyponatremia being obtained the correction of renal dysfunction (CI creatinine at discharge = 76 mL / min). In all cases, the Schellong test was negative, ruling out orthostatic hypotension.

DISCUSSION

Hyponatremia usually occurs within the first few days of treatment with thiazide diuretics but may also occur after months of treatment (6). Although thiazide-type and thiazide-like diuretics differ in chemical structure, they share the same mechanism of action, namely the inhibition of the Na-Cl co-transporter in the distal convoluted tubule (7). Currently, thiazide diuretics are a class of first-line drugs in the treatment of high blood pressure in the elderly.

Hospital admission for hyponatremia induced using thiazide diuretics is frequent, suggesting suboptimal monitoring, especially at the time of treatment initiation. According to the literature the ionogram should be obtained 7 to 14 days after thiazide initiation to detect the early onset of hypo-

natremia. There are case reports of hyponatremia occurring after years of treatment, suggesting the need for constant monitoring of patients on long-term treatment with thiazide diuretics (7). Our three cases exemplify these situations - early or late occurrence of hyponatremia after indapamide treatment. Previous values for electrolytes were not available until hospital admission.

There are numerous studies aimed at identifying the causes of hyponatremia in the elderly. The most common cause is the syndrome of inappropriate antidiuretic hormone (SIADH) (8, 9), closely followed by the treatment with thiazide-type and thiazide-like diuretics (7, 10). However, the accurate determination of the etiology of hyponatremia in a frail elderly patient should also consider other causes more rarely encountered in other age groups.

The presence of comorbidities may play an independent role in triggering hyponatremia, with attention being paid to neoplasia. There are studies that associate the presence of hyponatremia (especially the euvolemic and hypovolemic forms) with a significantly increased mortality among patients diagnosed with lymphoma, breast cancer, colorectal and pancreatic cancer, bronchopulmonary cancer, and hepatocellular carcinoma (11, 12, 13, 14).

The presence of comorbidities is always associated with polymedication (> 5 different drugs per day) (3, 15), which is a known risk factor for iatrogenic hyponatremia, the most commonly incriminated being the thiazide-type and thiazide-like diuretics. Angiotensin converting enzyme inhibitors are among the most prescribed drugs together with thiazide diuretics (2), followed by sartans, non-steroidal anti-inflammatory drugs and antidepressants (which affect water homeostasis), raising the hypothesis of drug interaction as a possible cause of hyponatremia. It should be noted that the presence of hypokalemia is frequent in patients with thiazide-induced hyponatremia (1).

Older age (1), female gender and low body mass index (10) are other risk factors for hyponatremia in patients treated with thiazide diuretics (6); to these must be added the non-compliance with drug therapy, often associated with varying degrees of cognitive disturbance, and the phenomenon of self-neglect, elements that will interfere with the rate of administration and the doses of recommended drugs (16).

Finally, we should make a special mention of the frail elderly patients requiring surgery, most commonly hemiarthroplasty for hip fracture, who frequently develop moderate hyponatremia perioperatively mainly due to the recommendations for preoperative water restriction (4, 5).

Symptoms of hyponatremia in frail elderly patients are polymorphic, represented by same-level fall preceded or not by vertigo, fatigue, confusion, nausea, vomiting, and neurological symptoms (7). In patients with acute hyponatremia, nausea, vomiting and headache due to cerebral edema (1) are more common, as in our Case 1. Unfortunately, these symptoms are commonly attributed to other concomitant diseases or other overlapping acute events, with a delayed detection of hyponatremia and an often incorrectly identified etiology. Iatrogenic pathology and dehydration should be the main causal lines given the increased thiazide-type and thiazide-like diuretic prescription for in the elderly and the hypovolemic status of the elderly. Thus, in the management of hyponatremia the first gesture is discontinuing the thiazide (if present in the therapeutic regimen), which is both diagnostic and therapeutic test. Attention should be paid to the slow cor-

rection of the imbalance in order not to induce osmotic demyelination, with severe neurological consequences (5).

CONCLUSIONS

With these cases we underlined the fact that treatment with thiazide-type or thiazide-like diuretics in the elderly requires frequent monitoring of electrolytes given the high risk of severe hyponatremia, clinical condition with atypical or less symptomatic clinical picture which delays (sometimes with fatal outcomes) the diagnosis. Considering an iatrogenic cause (most commonly induced by thiazide-type or thiazide-like diuretics) should be in the forefront of physician's mind, but it requires a thorough medical history, assessment of patient compliance and cognitive status as well as support from patient's family. Identification of the cause of hyponatremia should prevent recurrences and provide adequate patient education to prevent secondary, severe complications.

THERAPEUTIC PARTICULARITIES IN AMIODARONE INDUCED THYROID DISORDER IN PATIENTS WITH UNDERLYING CARDIAC CONDITION (Abstract). **Aim:** the analysis of therapeutic approach in patients with basic heart condition and amiodarone induced thyroid dysfunction – correlations with the evolution and prognosis. **Material and methods:** The study included 215 patients, 90 men and 125 women aged between 35 and 87, with different cardiac pathologies hospitalized in the Cardiology Clinic between 2004 -2014, who received amiodarone treatment, in most cases for prophylaxis of various arrhythmias, both supraventricular and ventricular. During the evolution, these patients have developed amiodarone-induced thyroid dysfunction (hypo- or hyper function). **Results and discussion:** The evaluation of thyroid function after starting treatment was performed in 187 patients (86.97%). Diagnosis of amiodarone-induced thyroid dysfunction was based on hormonal dosages of TSH, FT4 and FT3, endocrinological examination and thyroid ultrasound. Thyroid dysfunction treatment was initiated, depending on the situation, in all patients during the hospitalization. Treatment included anti thyroid drugs or hormones substitution and in some cases a minimal dose of prednisone. **Conclusions:** Thyroid dysfunction regardless of the type (with hypo- or hyper function) requires continuous changes of the cardiovascular treatment, and association, where appropriate, with thyroid dysfunction medication. In some cases the latter determines cardiovascular side effects, for instance corticotheraphy may become a factor of imbalance for the hemodynamic status of the patient (by fluid retention, increased blood pressure, hyper glycemia). **Keywords:** AMIODARONE, THYROID HORMONES, ANTI THYROID DRUGS

Amiodarone is a class III anti arrhythmic drug (according to the classification of Vaughan Williams) which is effective in the treatment and prophylaxis of arrhythmias, supra ventricular and ventricular (especially those that are life-threatening) (1). Apparently, it presents structural similarities with the thyroxin hormone produced and released by the thyroid gland (1, 2, 3, 4, 8). Thyroid abnormalities were observed in 14-18% of patients receiving the low dose of amiodarone (1, 2, 3, 8). Thyroid effects are variable: abnormal thyroid function tests detected only by

periodic laboratory control (TSH, FT4, FT3) in the absence of any clinical manifestations or thyroid clinical dysfunction: amiodarone-induced thyrotoxicosis form, or hypothyroidism. Both can occur on a previously normal thyroid gland or in the context of a pre-existing thyroid impairment that may worsen (2, 3, 4, 5, 8, 9).

Mechanism of amiodarone activity on thyroid hormones levels is particularly complex: Amiodarone inhibits 5'-deiodinase and thereby decreases the peripheral conversion of T4 in T3. Their renal elimination also decreases, T4 level increase and T3 decrease by about 25%, T4 and T3 entry in peripheral tissues is also inhibited. T4 levels increase by 40% in the first 1-4 months of treatment with amiodarone (10, 11, 12). An inhibition of the pituitary deiodinase can be seen after 3 months of treatment and leads to higher levels of thyroid stimulating hormone (TSH). Amiodarone, together with its metabolite, also have a direct cytotoxic effect on the thyroid follicular cells, the result being a destructive thyroiditis. It acts as a competitive antagonist of T3 at the cardiac level (3, 4, 6, 7, 8, 9, 13, 14, 15).

Amiodarone-induced thyroid impairment (AIT) can resemble the clinical and biochemical picture of either hypothyroidism or hyperthyroidism. Amiodarone - induced hyperthyroidism may be of two types: Type 1 AIT occurs in patients with an underlying thyroid pathology such as autonomous nodular goiter or Graves' disease - in these patients, there is accelerated thyroid hormone synthesis secondary to the iodide load from the amiodarone therapy (the Jod-Basedow phenomenon) (15); Type 2 - appears as a destructive inflammatory process followed by destruction in patients with a previously normal thyroid. It is a destructive thyroiditis with preformed hormones releasing from the damaged thyroid follicular cells (10, 11, 13, 14, 15). This type of development requires specific therapeutic management that involves the administration of glucocorticoids. Combined forms of thyroid impairment are rare (10, 11, 12, 13, 15). The thyrotoxic phase may last several weeks to several months, and it is often followed by a hypothyroid phase with eventual recovery in most patients. For unclear reasons, the toxic effects of amiodarone may take two to three years to manifest (10, 11).

This study analyzes the therapeutic particularities in amiodarone-induced thyroid dysfunction in patients with severe underlying heart disease in order to improve long-term prognosis.

MATERIAL AND METHODS

The study included 215 patients hospitalized in the Cardiology Clinic of "Sf. Spiridon" Hospital Iasi between 2004-2014, who received amiodarone treatment, mostly for prophylaxis of various arrhythmias, both supraventricular and ventricular. The group included 90 (41.86%) men and 125 (58.13%) women aged between 35 and 87 (fig. 1).

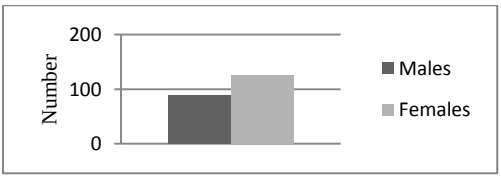

Fig. 1. Gender distribution of patients

Basic cardiac pathology of the study group included: acute viral myocarditis - 2 (0.93%) cases, acute myocardial infarction -16(7.44%) complicated with supraventricular arrhythmias (atrial extra-systoles, paroxysmal atrial fibrillation), systematized ventricular extra-systolas (bi, trigeminy) and ventricular tachycardia, other forms of

ischemic heart disease – 11 (5.11%) cases, ischemic dilated and toxic cardiomyopathy - 49 (22.79%) cases, hypertension - 76 (35.34%) cases complicated with atrial and ventricular arrhythmias (fig 2). In 60 patients (27.9%) it was performed electrical cardio version to convert atrial fibrillation to sinus rhythm and amiodarone was administered pre- and post-cardio version using a standard protocol.

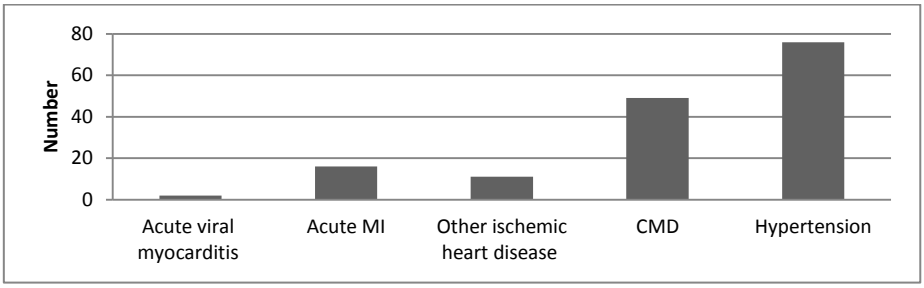

Fig. 2 Basic cardiac pathology of the study group

Patients were assessed clinically (heart auscultation, assessing signs of cardiac decompensation) and laboratory (12-lead electrocardiogram, echocardiography 2D, M mode and Doppler, chest radiography and laboratory data common in patients with heart disease: renal function and electrolytes, liver function, cardiac enzymes). Since patients were going to receive amiodarone in the treatment regimen, thyroid function was investigated for all by dosing routine hormone (TSH, FT4, FT3) prior to treatment.

RESULTS AND DISCUSSION

The administration of amiodarone was mostly in the load form - 800-1200 mg/day for 7-10 days followed by maintenance dose 200 mg (1 tablet/day 5-7 days/week (1 -1.4 g/week). In some patients the initial administration was intravenous, within 24 hours, because a rapid action was required.

Duration of treatment until the time of discovery of thyroid damage was between 6 months and 8 years. In all patients the thyroid function was investigated prior to the administration of amiodarone (TSH, FT4 and FT3 levels that were within normal limits). Evaluation of thyroid function after starting treatment occurred in 187 (86.97%) patients. Diagnosis of amiodarone - induced thyroid dysfunction was based on laboratory data – i.e. dosing TSH, FT4 and FT3.

Amiodarone - induced hypothyroidism has been diagnosed clinically in 39 (20.85%) patients and confirmed by elevated levels of TSH and low levels of FT4. Thyrotoxicosis occurred during Amiodarone treatment in 13 (6.95%) patients (fig 3). In all cases of thyrotoxicosis TSH level was low with FT4 normal or increased. 2 patients presented undetectable TSH values with FT4 and FT3 greatly increased (in one case with FT4 100 IU/ml). In 7 patients with thyrotoxicosis ultrasound showed a hypervascularization of thyroid (thyrotoxicosis type 1) and in 6 cases the vascularization was decreased or absent (thyrotoxicosis type 2). Thyroid ultrasound was abnormal only in 16 patients with amiodarone-induced hypothyroidism: enlargement of the thyroid, hypoechogenic areas. In the remaining patients, the thyroid ultrasound investigation was not performed.

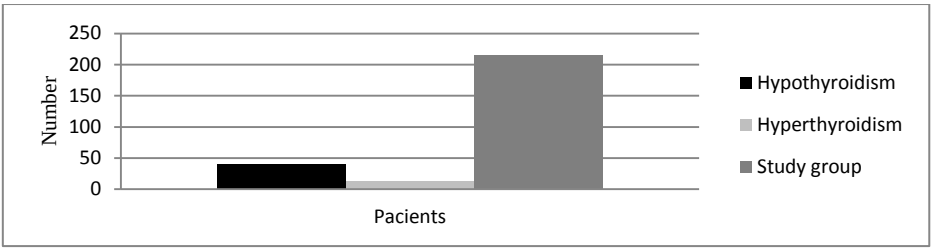

Fig. 3. Patients with amiodarone thyroid dysfunction

All patients with amiodarone-induced thyroid dysfunction were monitored initially in hospital for a period depending on the particularities of each case (between one week and one month). Thyroid dysfunction treatment was initiated, if necessary, in the hospital.

The first evaluation was performed after one month, and at 3, 6 and 12 months afterwards and consisted of clinical examination, electrocardiogram, echocardiogram, TSH and FT4, FT3 determination. In patients receiving Methimazole, monthly blood counts were indicated. Also, in patients receiving prednisone, the blood glucose and lipid profile were monitored. The patients were evaluated than annually.

For patients who confirmed the diagnosis of hypothyroidism we still maintained amiodarone in the treatment plan and we associated Levothyroxine in gradually increasing doses (25 μg/day 7 days, than 50 μg/day, up to one month after the patient was assessed once again). One month evaluation revealed: normalization of TSH and FT4 (all patients) and normalization of the thyroid ultrasound aspect. Evaluation at 3 and 6 months showed normal levels of thyroid hormones; we continued the initial dose of Levothyroxine. All patients maintained normal thyroid function at 12 months under a minimum dose of Levothyroxine. No patient required a dose more than 50 μg/day.

For patients diagnosed with amiodarone - induced thyrotoxicosis it was necessary to replace amiodarone with another anti arrhythmic drug and start treatment with Methimazole (doses between 10-40 mg/ day) or/plus prednisone. The evolution of these patients was unpredictable; in 25 % of cases, after a variable period of time (3 to 6 months) they developed hypothyroidism (TSH greatly increased) which imposed a temporary elimination of anti thyroid drugs. After a short period of hypothyroidism (3 months), 3 patients presented thyrotoxicosis relapse, which led to the resuming of treatment with anti thyroid drugs. Only one patient in this group needed thyroidectomy.

Amiodarone-induced thyrotoxicosis was more common in male patients, which presented an evolution and a very unfavorable prognosis: 2 patients had atrial fibrillation and atrial flutter with rapid ventricular rate (over 150/min) resistant to anti arrhythmic treatment, and another two patients died due to worsening heart failure phenomena evolving to cardiogenic shock and refractory acute renal failure.

Patients diagnosed with amiodarone-induced hypothyroidism had a somewhat favorable evolution after hormone replacement. Levothyroxine therapy improved the clinical picture of hypothyroidism in all patients without requiring discontinuation of amiodarone in any of the cases.

The side effects related to the medication of thyroid dysfunction in the study group were the following:

- 3 patients (one male and two females) had moderate leucopenia (between 2,800-3,400/mm^3) that could be related to the treatment with Methimazole - no therapeutic intervention was required;

- In the group of patients treated with Levothyroxine no major adverse effects were observed, only in 5 cases heart rate increased, unjustified by any other situation;

- In two patients (one male and one female) who received the combination of Methimazole and prednisone high blood glucose levels were observed between 2 weeks and 2 months after the initiation of corticotherapy, but not exceeding 150 mg/dl; one of the patients presented as well high values of blood pressure.

CONCLUSIONS

Amiodarone - induced thyroid dysfunction requires immediate therapy. Our study showed that hypothyroidism amiodarone-induced generally had a better prognosis after hormone replacement therapy and did not require removal of anti arrhythmic regimen, thyroid dysfunction in this case being solved only by the introduction of thyroid hormone replacement therapy.

However, Amiodarone-induced thyrotoxicosis proved to be a severe clinical presentation, worsening heart failure by maintaining a high heart rate, generally resistant to anti arrhythmic drugs; it usually required the removal of amiodarone treatment and anti thyroid drugs; in all cases the evolution was slow and unpredictable, sometimes being fatal. Two patients had atrial fibrillation and atrial flutter with rapid ventricular rate (over 150/min) resistant to anti arrhythmic treatment, and another two patients died due to worsening heart failure. We consider thyroid dysfunction (either hypothyroidism or thyrotoxicosis) a negative element in the evolution of patients with pre-existing heart disease, not only by clinical worsening of the underlying disease, but also by the need to permanently review the cardiovascular treatment and the possible association with appropriate medication to the thyroid dysfunction. It is also necessary to consider the side effects of thyroid dysfunction medication, including corticosteroid treatment.

THE UTILITY OF LIPOPOLYSACCHARIDE-BINDING PROTEIN IN THE DIFFERENTIATION BETWEEN PERIPROSTHETIC JOINT INFECTION AND ASEPTIC LOOSENING?

The pre-operative differentiation between periprosthetic joint infection (PJI) and aseptic loosening after total hip (THA) or knee (TKA) arthroplasty is essential for successful therapy and relies in part on the use of molecular markers. A recent prospective, controlled, clinical trial study conducted by Friedrich MJ and collaborators assessed serum levels of lipopolysaccharide-binding protein (LBP) from one hundred and twenty patients presenting with a painful TKA or TKA with indication for surgical revision. Pre-operative blood and serum samples were collected and analysed also for white blood cell (WBC) count and C-reactive protein (CRP). The definite diagnosis of periprosthetic joint infection was determined on the basis of clinical, microbiological and histopathological examination. LBP showed significantly higher values in PJI compared with aseptic loosening ($p < 0.001$) and control ($p < 0.001$), with a specificity of 66 % and a sensitivity of 71 % at a cutoff value of >7 ng/ml. In combination with CRP, the positive predictive value for PJI was at 0.67; negative predictive value with both negative was at 0.77. The authors concluded that the use of LBP in serum appears not to be a more accurate marker than CRP level in serum for detecting PJ, and on the basis of these results, they cannot recommend the sole use of LBP for differentiating PJI and aseptic loosening following THA and TKA. (Friedrich MJ, Randau TM, Wimmer MD et al. Lipopolysaccharide-binding protein: A valuable biomarker in the differentiation between periprosthetic joint infection and aseptic loosening? *Int Orthop*. 2014 May 15. [Epub ahead of print]. PROGRESSIVE DYSPNEA- COMPREHENSIVE EVALUATION OF A COMMON SYMPTOM (Abstract): Dyspnea is one of the most common symptoms in the clinical setting, the main causes being represented by respiratory and cardiovascular disorders but sometimes it is difficult to identify and document the underlying mechanism of breathlessness. We present the case of a 75-years-old male patient, former smoker, with progressive worsening dyspnea. He performed a complex imagistic, respiratory, and functional assessment, the results showing severe emphysema with mild obstructive syndrome, in contrast with severe impairment of diffusing capacity of the lung for carbon monoxide (DLCO) due to inhomogeneous distribution of ventilation/perfusion ratio. This case brings to front a certain type of chronic obstructive pulmonary disease (COPD), with suggestive clinical exam but with minimal impairment of spirometry results in the presence of debilitating dyspnea. In order to perform an accurate diagnosis, alternative functional diagnostic measurements, like estimation of DLCO, should be used.
Keywords: DYSPNEA, EMPHYSEMA, COPD, DLCO.

Dyspnea or shortness of breath is one of most common symptom in clinical setting, being defined as"a subjective experience of breathing discomfort that consists of qualitatively distinct sensations that vary in intensity" (1). The main causes are represented by respiratory and cardiovascular disorders but sometimes it is difficult to identify and document the underlying mechanism of breathlessness.

CASE REPORT

We report a case of a 75-years-old man, repeatedly admitted in Pulmonary Rehabilitation Clinic of the Iaşi Rehabilitation Clinic Hospital, in July and September 2013, for inclusion in the pulmonary rehabilitation program. The patient has experienced progressive worsening dyspnea in the last two years. He was a heavy smoker (50 pack-years) but he quitted two years ago. His personal medical history included arterial hypertension grade 2, associated with high cardiovascular risk because of his age, male sex, dyslipidemia and impaired fasting glycemia, and a basal cell carcinoma of the left nasogenian region, surgically removed.

Clinical exam revealed a slight barrel chest, hyperresonant chest wall percussion

and diminished vesicular breath sounds, as well as blood pressure values adequately controlled by amlodipine 10 mg daily.

Peripheral arterial oxygen saturation (S_pO_2) was 88-90% on room air, decreased at 82% during the 6-minute walk test, while lab values showed polycythemia (Hb 18.21 g/dL, Ht 54.34%), most probably as a result of chronic hypoxemia. Radiologic imaging of the lungs (chest X-ray, computer tomography) revealed severe bilateral emphysema (fig. 1).

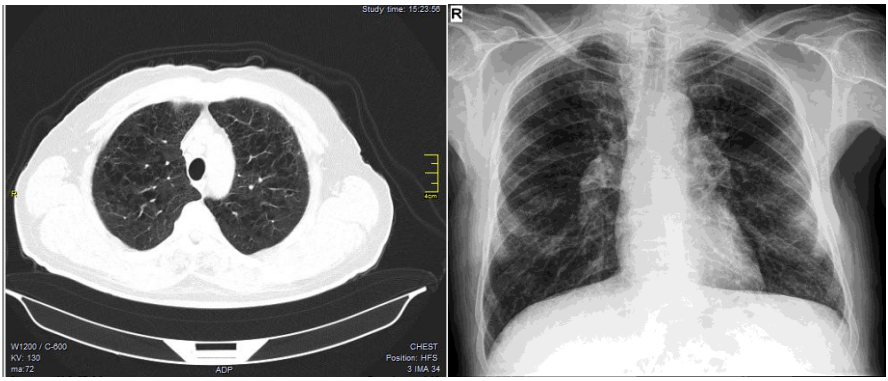

Fig. 1. Radiologic aspect of lungs parenchyma, showing severe bilateral emphysema (thoracic CT–left, chest X-ray-right)

The patient performed a complex respiratory and functional assessment in our clinic, according to the current guidelines (2), and also in other medical services, that included subjective assessment of dyspnea on Borg and modified Medical Research Council Dyspnea (mMRC) scale, the COPD Assessment Test (CAT), 6-minute walk test, spirometry, diffusing capacity of the lung for carbon monoxide (DLCO), body plethysmography, echocardiography.

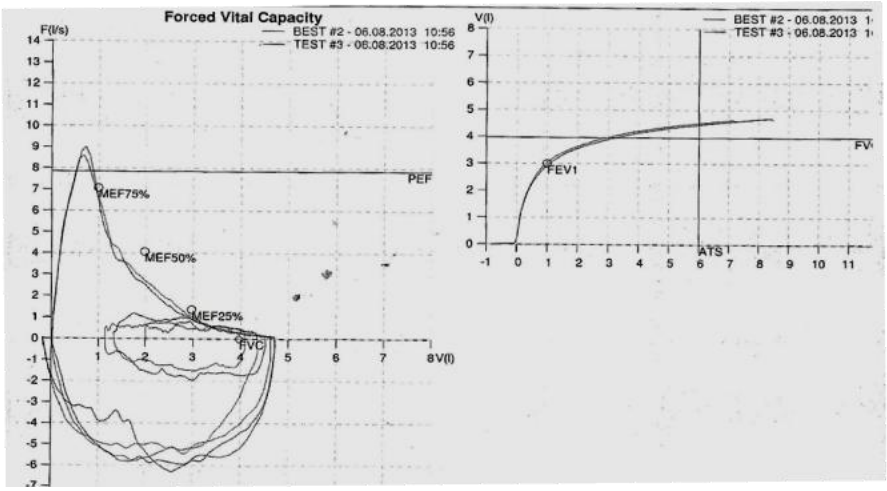

Fig. 2. Spirometry (displaying mild obstruction)

The main findings were a severe perception of dyspnea (Borg scale 7-8, mMRC scale 4) and a very high impact level of disease on daily living activities (CAT 30), a mild obstructive syndrome (FEV_1/FVC 68%, FEV_1 101%), decreased mid-expiratory flows (MEF_{50} 52% from predicted, MEF_{25} 39% from predicted) (fig. 2) and a small increase of residual volume (RV 3.34 L, 121% from predicted), with normal values for central airways resistance (Raw 1.95 cmH2o/l/s) and total lung capacity (TLC 7.87 L, 110% from predicted). There were no signs of pulmonary hypertension or right heart involvement detected by cardiovascular ultrasound.

The most prominent findings came from DLCO, showing a severe decrease of DLCO adjusted for hemoglobin (DLCO 6.37 ml/min/mmHg, 24% from predicted) and DLCO/VA ratio (DLCO/VA 27% from predicted) (fig. 3).

DISCUSSION

Spirometry is the basic evaluation method of pulmonary function when a history of smoking and dyspnea are present in a male patient. Sometimes, there is an imbalance between spirometry results and clinical picture, like in our case. Despite the severe dyspnea, this former smoker had some clinical signs of pulmonary emphysema at initial evaluation, radiologically confirmed, but only borderline obstructive pattern of spirometry, more accentuated in distal airways, and a small increase of the residual volume on body plethysmography. Also, episodes of exacerbations in this clinical case were scarce. In order to refine the diagnosis it was performed single-breath CO diffusing capacity test that revealed severe impairment of DLCO due to inhomogeneous distribution of ventilation/perfusion ratio. This finding raised the question whether some other concurrent clinical conditions, such as pulmonary hypertension through obliteration of the pulmonary arterioles or the involvement of the pulmonary capillary bed in the setting of a systemic vascular disease were existing (2), but none of these was confirmed.

These data revealed a chronic obstructive pulmonary disease (COPD) and accordingly to revised GOLD guideline the patient was in the GOLD 1 stage, class B of risk. It is well-known that patients with COPD have a large heterogeneity in their clinical presentation, and recently it was proved that it comes from genetic basis. Data from COPD Gene Study showed that there are four subgroups of smokers, associated with clinical symptoms, including exacerbations and dyspnea, and with known COPD-associated genetic variants. These groups are: the relatively resistant smokers, without or with mild emphysema despite heavy smoking, smokers with mild upper zone emphysema-predominant, those with airway disease predominant and the patients with severe emphysema, the latter group being strongly genetically associated with rs8034191 in the chromosome 15q region (3).

Furthermore, emphysema is a term derived from pathology, the modified lungs structure being a result of protease-antiprotease imbalance, followed by the protease-mediated destruction of elastin and the destruction of the gas-exchanging structures. The diagnosis is often used in practice but rarely well-documented. In COPD, the relative contribution of obstructive bronchiolitis and emphysema varies from patient to patient. Pulmonary emphysema is more associated with gas transfer abnormalities than with decreased FEV_1, as in our case, so that the measurement of DLCO provides valuable information on the functional impact of chronic pulmonary disease, being more useful than spirometry in patients with breathlessness and a mild degree of airflow limitation (4).

CONCLUSIONS

This case brings to front a certain type of COPD, with suggestive clinical exam but with minimal impairment of the spirometry values in the presence of debilitating dyspnea. In order to perform an accurate diagnosis, alternative functional diagnostic measurements, like estimation of DLCO, should be used. Additionally, future development of the genetic testing will allow early identifying of the particular subtype of smokers that will develop a pattern of very severe obstructive emphysema, in order to close monitoring and initiating motivational preventive programs to them to determine them to quit smoking, through counseling and medication.

JUVENILE IDIOPATHIC ARTHRITIS AND ANTHROPOMETRIC MEASUREMENTS, BODY COMPOSITION, AND NUTRITIONAL PARAMETERS

A group of researchers from Department of Paediatrics, Turku University Hospital, Turku-Finland conducted a study that assessed the effect of juvenile idiopathic arthritis (JIA), its subtypes and disease activity on anthropometric measurements, body composition, and nutritional parameters. A cross-sectional cohort of 40 JIA patients, aged 3-10 years, was compared with 40 healthy children matched for age and gender. Concentrations of nutritional and inflammatory biomarkers in the blood, anthropometric measures, and clinical status were recorded and the parents filled in a 7-day food diary and completed the Childhood Health Assessment Questionnaire (CHAQ). The JIA patients had low disease activity: 60% had inactive disease, the median CHAQ score was 0.125, and the median erythrocyte sedimentation rate (ESR) was 6 mm/h. Significantly higher values for central and peripheral adiposity were found in JIA patients compared with in healthy controls, and obesity/overweight was more common despite no differences in weight-for-height. The intake of energy (kcal/day) was significantly higher in the JIA patients ($p = 0.036$). The nutritional biomarkers were comparable in both groups. The JIA subtype and disease activity did not affect body composition, energy intake, or the nutritional biomarkers. They concluded that even JIA patients with low disease activity had a higher central and peripheral adiposity and a higher energy intake than their healthy peers and neither disease subtype nor disease activity had any association with changes in body composition.(Grönlund MM, Kaartoaho M, Putto-Laurila A, Laitinen K. Juvenile idiopathic arthritis patients with low inflammatory activity have increased adiposity. *Scand J Rheumatol*. 2014 Sep 2:1-5. [Epub ahead of print]. PMID: 25178152)

PAIN MODULATION BY CURCUMIN AND ASCORBIC ACID IN MICE

A. Luca [1,2], Teodora Alexa[1,2], A. Dondaş[2], Georgiana Andron[2], Magda Bădescu[1], Ioana Dana Alexa[3], Cătălina Bohotin[1,2]

PAIN MODULATION BY CURCUMIN AND ASCORBIC ACID IN MICE (Abstract) **Aim:** The present study aims to evaluate whether ascorbic acid (AA) and curcumin, two substances with redox properties, have similar effects on different models of pain in mice. **Materials and methods:** This study included a total of 28 mice that were divided into four groups. One group (AA) received intraperitoneally 500 mg/kg b.w. AA for 21 days and the 2-nd group (curcumin) received 120 mg/kg b.w. curcumin by gastric gavage for two weeks. Other two groups serve as control and received vehicle in a dose – time manner similar to that of the treated groups. The pain models (oro-facial formalin induced pain, paw formalin induced pain and visceral pain) were performed 24 h after the last dose. **Results**: when compared with control groups, curcumin significantly decreases pain perception in oro-facial (p=0.01 1-st phase, p=0.002 2-nd phase) and paw formalin induced pain (p=0.04 1-st and 2-nd phase) while AA stimulates pain perception in acid acetic induced visceral pain (p=0.05) and increases oro-facial inflammatory pain induced by formalin (p=0.02) but demonstrates analgesic effects on paw formalin induced pain (p=0.003 1-st phase, p=0.01 2-nd phase). **Conclusions:** ROS production is important in pain modulation. Structures involved in the process of pain have different antioxidant defense capacities. Curcumin and AA are able to modulate pain perception, but beside their antioxidant capacities, there are other mechanisms involved.
Keywords: CURCUMIN, ASCORBIC ACID, PAIN, ANALGESIA.

According to recent studies, reactive oxygen species (ROS) are reported to be associated with chronic pain, especially neuropathic and inflammatory (1). They are also closely related to central sensitization and the elevated ROS in the spinal cord and colon have proven to be involved in visceral pain (2).

Recent studies suggest that oxidative stress and the balance between oxidants and antioxidants can be directly involved in certain diseases characterized by different types of pain or inflammation (3).

Curcumin, a hydrophobic polyphenol, protects mitochondrial dysfunction and modulates endogenous antioxidant enzymes, scavenges ROS and NO-based radicals, neutralizes ROS and RNS-based radicals and increases the synthesis of glutathione. On the other hand, several studies demonstrate that curcumin has pro-oxidant capacities through its ability to increase oxidized glutathione (GSSG) and to also reduce glutathione (GSH), thus decreasing

the GSH/GSSG ratio (4).

It was demonstrated that ROS are involved in the apoptosis induced by curcumin in A549 lung adenocarcinoma cells, but also that curcumin prevents the mitochondrial dysfunction and suppresses the ROS increase (5).

Curcumin seems to have analgesic proprieties, but the mechanism by which it induces antinociception is not clear. Activation of K (ATP) channels (6) or transient receptor potential vanilloid 1 (TRPV1) activation have been proposed (7). Ascorbic acid (AA) is an important antioxidant known to quench ROS, and its oxidase form dehydroascorbic acid (DHA), enters mitochondria via facilitative glucose transporter 1 (Glut1) and accumulates in the mitochondria as ascorbic acid (mtA). The accumulation of AA in the mitochondria inhibits the oxidative mitochondrial DNA damage and thus AA may be useful in generating therapies by antagonizing the effects of ROS (8).

Although AA has a controversial role in pain therapy, it has been shown that a combined antioxidant therapy can be safe and efficient in pain relief for patients with chronic diseases (9).

The purpose of our study was to evaluate if, by modulating ROS production through two antioxidant substances (AA and curcumin), similar effects will be obtained on different models of pain (orofacial formalin induced pain, paw formalin induced pain or the acetic acid induced visceral pain).

MATERIAL AND METHODS

Animals. The experiments were conducted using male BALB/c mice (28-34 g), housed at 21 ± 2 °C under a 12-h light/dark cycle, with access to food and water ad libitum. All animals were habituated to the testing laboratory for at least five days. The experimental protocols and procedures described in this article complied with the European Communities Council Directive 86/609/EEC and followed the International Association for the Study of Pain's (10) and the University of Medicine and Pharmacy "Grigore T. Popa" ethical guidelines for investigations of experimental pain in conscious animals.

Drugs. The drugs used in these experiments were: vitamin C intravenous solution 750mg/5 ml (Arena, Romania), 37% formaldehyde (Fluka, Germany), acetic acid (Sigma, Germany) and Curcumin (Turmeric powder, Sigma, Germany). AA was freshly diluted in distilled water to avoid precipitation and was disposed after first use to avoid oxidation. Curcumin was freshly prepared in olive oil.

The acetic acid induced visceral pain. Writhing Test (WT test) was performed as described by Koster *et al*. (11). After acclimatization in an acrylic observation chamber for at least 20 minutes, the mice received 0.1 ml /10 mg kg b.w. i.p. injections with 1.0% (v/v) acetic acid (12). A writhe was defined as a contraction of the abdominal muscles accompanied by an extension of the forelimbs and elongation of the body.

The paw formalin test (PFT). The mice were injected with 20 μL of 5% formalin (from 37% formaldehyde) subcutaneously into the plantar surface of the right hind paw using a microsyringe. Pain and inflammatory response was measured by the total time (in seconds) spent by mice licking and/or biting the injected paw during periods of 0–9 min (first / neurogenic phase) and 10–40 min (second / inflammatory phase) (13).

The orofacial formalin test (OFT). Nociception induced by formalin was performed as described by Luccarini *et al.* (14). Animals received 20 µL of 5% formalin into the right whisker pad. The nociceptive score was determined by recording the number of seconds the animals spent grooming the injected area with the ipsilateral hind paw or forepaw, often accompanied by the contralateral forepaw, for the first 6 min (first / neurogenic phase) and from 7 to 40 min (second / inflammatory phase).(15)

Study design. The study used a total of 28 mice that were divided into four groups: group AA mice receiving intraperitoneal 500 mg/kg b.w. AA for 21 days. Group Curcumin receiving two weeks curcumin in combination with oil by intragastric gavage 120 mg/kg b.w. The other two groups that served as control received an equal volume of distilled water (AA Control), olive oil (Curcumin control) respectively in the same time manner. All tests were performed 24 h after the last dose.

Statistical analysis. The data obtained were expressed as the mean value ± SEM. Statistical evaluations were performed using *SPSS 20.0* software One-way analysis of variance (ANOVA) and Student's t-test for independent variable were used to assess within and between groups variability. The significance level of the results was set at $p<0.05$.

RESULTS

The effects on paw formalin induced pain. Curcumin has shown an analgesic effect on both phases on the formalin induced pain (phase 1 p=0.04 respectively phase 2 p=0.04) when compared with control group (fig. 1). AA has also demonstrated an analgesic effect on both phases (p=0.01) as compared with control group (fig. 2). No significant differences were observed between curcumin and AA groups.

The effects on orofacial formalin induced pain. The analgesic effect of curcumin was statistically significant in both phases (phase 1 p=0.01, phase 2 p=0.01 respectively) when compared with control group (fig. 1).

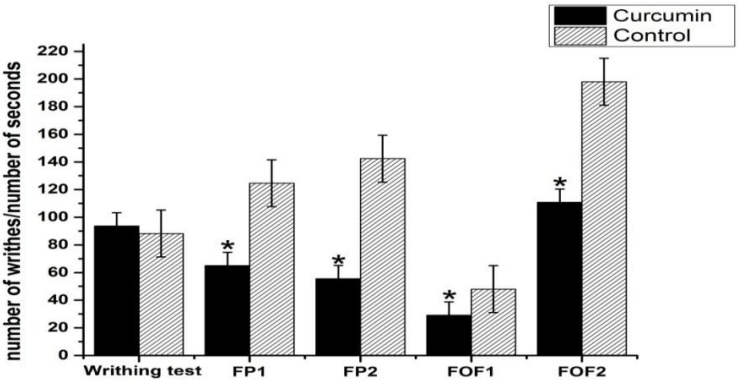

Fig.1. Effects of 14 days treatment with curcumin on the writhing test and phases 1&2 of the orofacial (FOF) and paw (FP) formalin tests. The results are expressed as mean± S.E.M. * $p < 0.05$ as compared with control group

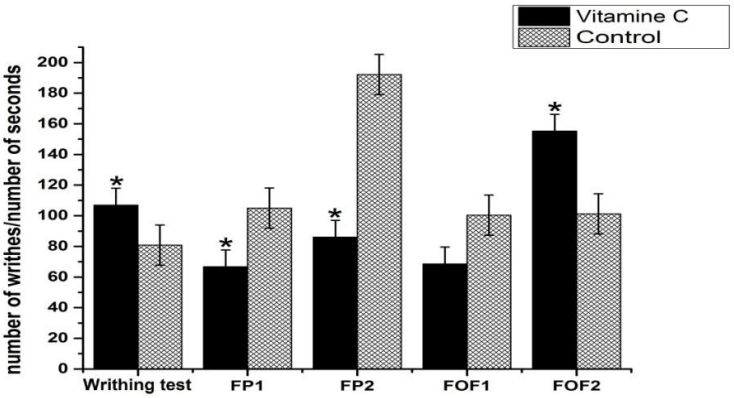

Fig. 2. Effects of 21 days treatment with AA on the writhing test and phases 1&2 of the orofacial (FOF) and paw (FP) formalin tests. The results are expressed as mean± S.E.M.* $p < 0.05$ as compared with control group

By contrary, AA has no effect on the first phase, increases pain perception on the second phase (p=0.01), as compared to the distilled water group. Significant differences were observed between curcumin and AA groups in the first phase. (p =0.007).

The effects on visceral pain. Although curcumin has shown potential on orofacial and paw formalin induced pain, the effect on visceral pain had no statistical significance (fig. 1). However, AA stimulates pain perception compared to the control group (p=0.05) (fig. 2).

DISCUSSION

In our study, we demonstrated that long term administration of curcumin and AA modulate pain perception in formalin and acetic acid induced pain. Thus, curcumin significantly decreases pain perception in oro-facial and paw formalin induced pain, while AA has an analgesic effect on paw formalin induced pain. On the contrary, AA increases the oro-facial inflammatory pain induced by formalin and visceral pain.

Under physiological conditions, AA mainly exists in its reduced form and in trace quantities in the oxidized form, dehydroascorbic acid (DHA). Beside its antioxidant capacities, AA seems to down-modulate NF-KB signaling (15), as well as norepinephrine production (16).

Chen and collaborators have shown that AA might generate H_2O_2-dependent cytotoxicity toward a variety of cancer cells in vitro and in vivo, without adversely affecting normal cells (17), while Martinovich *et al* suggested that Ca (2+) release in HEp-2 cancer cell line is the mechanism through which AA increases mitochondrial ROS production (18). Thus there are enough evidences that AA has both pro and anti-oxidant capacities.

At the dose used in our study, AA seems to exert proprieties, having an anti-oxidant effect paw formalin induced pain and acting as a pro-oxidant on the inflammatory phase in orofacial formalin induced pain and the acetic acid visceral induced pain. Besides redox proprieties, we cannot exclude, that changes in epinephrine levels secondary to AA administration might be

involved in pain modulation. Indeed, it is well-documented that norepinephrine induces both antinociception by activation of the NO/cGMP/KATP pathway (19) and nociception by enhancing pain facilitation from the brain (20).

Our results suggest that AA has different effects on pain at the same dose. These effects depend probably on cells resistance to ROS production and on pain structures sensitivity to epinephrine stimulation.

Similar to vitamin C, curcumin, a mitochondrial modulator, has both pro- and antioxidant activities. The underlay mechanisms of curcumin effects are not clarified, but regulation of various molecular targets, such as nuclear factor-κB, inflammatory cytokines and other enzymes are implied (21).

In our study, curcumin had a significant antinociceptive effect on both phases of formalin induced pain, with no effect on visceral pain. Indeed, peripheral and central pathways for visceral pain are unique and some receptors such as acid sensing ion channels, sodium channels, calcium channels, kappa opioid receptor, appear to be particularly important to modulating pain. In addition to the acetic acid induced pain, nociceptive messages from the inflammated peritoneum involve neurokinin A rather than substance P as a mediator. By contrast, inflammatory phase in formalin induced pain is mainly mediated by substance P(22). Thus, the curcumin antinociceptive effects are not only a consequence of its antioxidant activity; other mechanism seems to be also involved. Considering everything, we have demonstrated that: ROS production might have a place in pain modulation; neuroanatomical structures involved in pain modulation have different antioxidant defense capacities and curcumin and AA are able to modulate pain perception, but there are other mechanisms involved, beside their antioxidant capacities.

CONCLUSIONS

By using two ROS modulators (ascorbic acid and curcumin), we demonstrated that oxidative stress might have an important place in pain pathophysiology. Further studies are however, however necessary to further explain the involvement of curcumin and ascorbic acid in pain modulation.

ORTHOSTATIC INTOLERANCE – AN EXPRESSION OF AUTONOMIC DYSFUNCTION IN PARKINSON'S DISEASE (Abstract): Orthostatic intolerance syndrome is an important issue, having multiple etiologies and being the result of an inadequate response to changing in body position, namely the transition from supine to standing, a process that causes a series of responses regulated by the autonomic nervous system. **Aim:** The aim of this study was to create a profile of patients with Parkinson's disease and orthostatic hypotension, a form of orthostatic intolerance, identifying the risk factors for this condition. **Material and methods:** We conducted a study on 41 patients with Parkinson's disease selected from 200 consecutive patients with orthostatic hypotension, hospitalized in Cardiology Clinic of Colentina Clinic Hospital which met the diagnosis criteria for orthostatic hypotension. In order to meet the inclusion criteria, all patients were evaluated according to a preset protocol: medical history, clinical and paraclinical examination, including neuro-psychiatric assessment and the orthostatic tolerance test. **Results and discussion:** The decline in standing blood pressure was related to the presence of hypotensive neurological drugs, especially Levodopa, in chronic treatment, but it was not influenced by age or cardiovascular co morbidities. There is an improvement in blood pressure both in supine and upright position at discharge when compared to admission values. **Conclusion:** The degree of decrease in the standing blood pressure values was correlated with the presence of potentially hypotensive neurological drugs, particularly Levodopa treatment, with a favorable effect of administration of non-pharmacological treatment and changes made in chronic neurological treatment. **Keywords:** ORTHOSTATIC HYPOTENSION, ORTHOSTATIC TOLERANCE TEST, PARKINSON'S DISEASE.

Orthostatic intolerance syndrome is an important issue, having multiple etiologies and being located on the border of several medical specialties, as diagnosis and treatment. After essential arterial hypertension, orthostatic hypotension is the most common disorder of blood pressure regulation in adults aged over 65 years, with prevalence between 5 and 30%, depending on the studied population and the used definition.

Prospective studies have shown that orthostatic hypotension is a predictive factor for ischemic stroke and all-cause mortality in elderly people (1-3).

This condition is one of the least understood manifestations of autonomic dysfunction, being the result of an inadequate response to changing in body position, namely the transition from supine to standing, a process that causes a series of responses regulated by the autonomic nervous system. The term"autonomic dysfunction" refers to any dysfunction of the autonomic nervous system - central, peripheral or secondary to other conditions (1,2).

There are two types of autonomic dysfunction- acute and chronic form. Chronic form can be divided into primary and secondary, the last one being more common. However, when failure dominates the clinical picture and a clear cause is not obvious, it is called primary dysautonomia. Primary dysautonomia, in its turn, can be divided into four syndromes: isolated pure dysautonomia, systemic nerve atrophy, Parkinson's disease with autonomic dysfunction (3) and Lewy body dementia, while secondary autonomic dysfunction, involving autonomous damage and disease makes its debut in the context of diabetes mellitus, amyloidosis or various polyneuropathies (4-6). While primary and secondary autonomic dysfunctions are caused by structural damages of the autonomic nervous system (either central or peripheral), drug-induced orthostatic hypotension is about functional impairment.

The clinical aspects that suggest the diagnosis at initial assessment are represented by the onset of the symptoms (dizziness, syncope) after switching from supine to standing, possibly after prolonged immobilization and the existence of a temporal relationship between the onset and a change in dosage of potentially hypotensive drugs, parkinsonism, presence of autonomic neuropathy or hypovolemia.

Effective treatment of orthostatic intolerance can be a challenge. The main therapeutic target consists of improving the symptoms in the transition from supine to standing position and functional status of the patient while reducing the risk of falls and syncope, being less oriented to strictly normalize the blood pressure levels.

MATERIAL AND METHODS

We conducted a study on 200 consecutive patients hospitalized in Cardiology Clinic of Colentina Clinic Hospital which met the diagnosis criteria for orthostatic hypotension as mentioned in the syncope guide of the European Society of Cardiology: a symptomatic reduction of the systolic blood pressure from baseline values with more than or equal to 20 mmHg or/and of the diastolic blood pressure with more than or equal to 10 mmHg, or a systolic pressure-lowering below 90 mmHg (3,5). To determine the blood pressure we used the active method (active standing), the orthostatic tolerance test being performed both on admission and at discharge, by measuring blood pressure and heart rate initially supine, then standing at 1, 3 and 5 minutes after changing position (4).

In order to meet the inclusion criteria, all patients were evaluated according to a preset protocol: medical history, clinical and paraclinical examination, including neuro-psychiatric assessment. All the patients with Parkinson's disease were further selected in order to create a profile of these patients and to identify the risk factors for orthostatic hypotension. These neurological patients were investigated before and after non-pharmacological treatment, assessment and adjustment of the current drugs.

Statistical analyze was done using the Microsoft Excel 2007 and *SPSS* for Windows programs.

RESULTS

The larger selection group diagnosed with orthostatic intolerance (n= 200 patients) consists of 107 women and 93 men. The Parkinson's disease study group included 41 patients, the gender distribution showing a slightly higher percentage of male patients (18 men vs 13 women), representing 19.35% of total male patients and 12.15% of females (fig. 1). The mean age of neurological patients was 76.41 years (64 - 86 years).

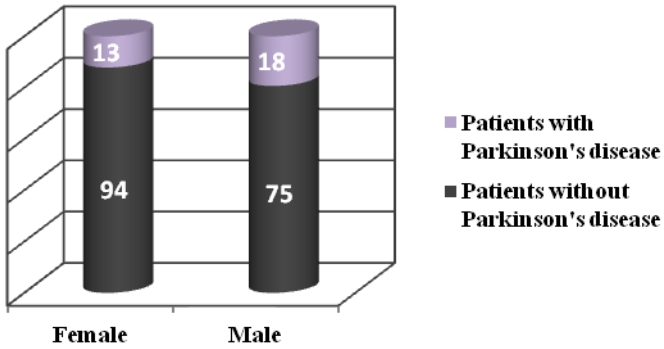

Fig. 1. The frequency of patients depending on the presence of Parkinson's disease

All the 41 Parkinson's disease patients were treated with neurological drugs, ten patients receiving also psychiatric medication, Levodopa being the most used agent in combined therapy (tab. I).

Average supine blood pressure on admission was 129/75 mmHg versus 127/72 mmHg at discharge (p=0.265) (fig. 2), while the lowest of standing blood pressure values at admission was 75/40 mmHg and at discharge was reaching 90/60 mmHg (p<0.001) (fig. 3).

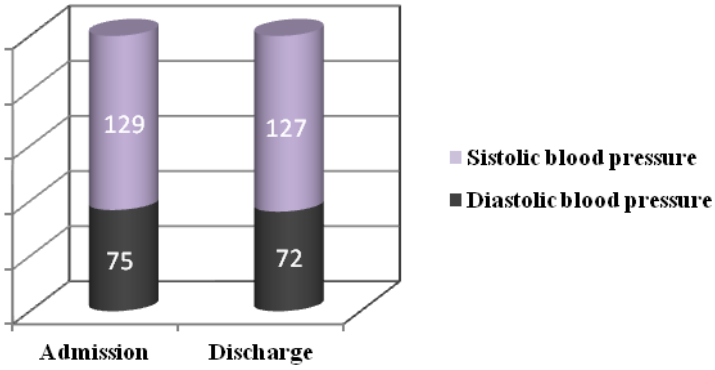

Fig. 2. Average supine blood pressure values

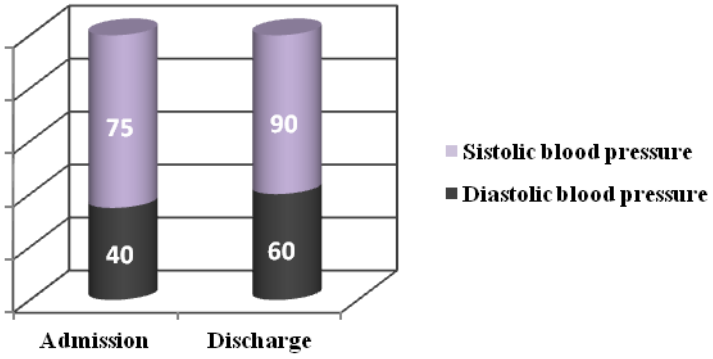

Fig. 3. Minimum of standing blood pressure values

Orthostatic tolerance test on admission revealed an average of 109/65 mmHg compared to 122/69 mmHg at discharge (p=0.007) (fig. 4).

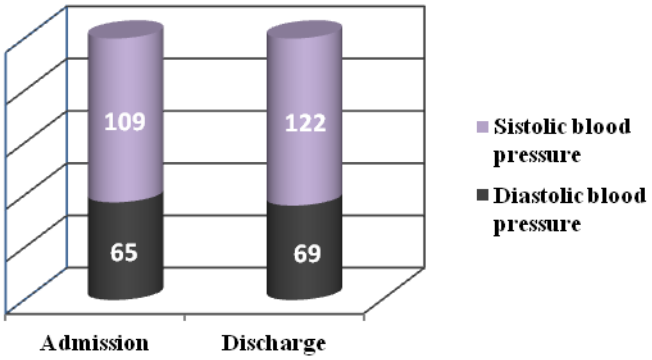

Fig. 4. Average of standing blood pressure values

There was no significant difference between the mean age of patients with orthostatic hypotension and those with negative tolerance test at the time of discharge (p= 0.929). Patients with persistent orthostatic hypotension at discharge had a prevalent cardiovascular history, compared to their counterparts without orthostatic hypotension, but the difference did not reach the statistical significance (p= 0.789).

All the patients received non-pharmacological treatment and 10% were treated with vasopressor agent Midodrine. Neurological medication is influencing the maintenance of orthostatic hypotension at discharge ($p < 0.05$), Levodopa having the most significant hypotensive effect ($p < 0.001$).

DISCUSSION

We used the analysis of postural changes in blood pressure values in order to find responsible modifiable factors that influence this type of pathology and to determine the frequencies for the studied group.

It is known that in Parkinson's disease, the prevalence of orthostatic hypotension is between 43 % and 58 % and may reach up to 60 % in some studies (7). Two factors could explain this high prevalence: first, dopaminergic drugs that may induce or aggravate orthostatic hypotension, and, second, Parkinson's disease dysautonomia (8, 9).

Our Parkinson's disease study group had a relatively homogenous gender distribution and a high mean value of age (76.41 years) which probably contribute to orthostatic hypotension. Also, the degree of decrease in the standing blood pressure values was correlated with the presence of potentially hypotensive neurological drugs, Levodopa being the most powerful contributor to this phenomenon, these findings being supported by several previous studies (7).

Age and cardiovascular co morbidities were not influential over the presence of orthostatic intolerance, as we would have expected, but we had not perform a detailed analyze of these cardiovascular diseases and their hemodynamic effects.

Despite these facts, the results showed a significant improvement of blood pressure values in both supine and upright position

at discharge, compared to values determined on admission, for these neurological patients. This favorable outcome is even more relevant as it could not be explained by the use of vasopressors, as long as only 10% of patients were receiving Midodrine.

The reasonable explanation for the improvements in blood pressure values both in supine and upright position at discharge, when compared to the values measured on admission, remains the adjustment of concomitant hypotensive medication and the association of non-pharmacological treatment, which were performed in all patients.

CONCLUSIONS

The results indicate that the degree of decrease in the standing blood pressure values was correlated with the presence of potentially hypotensive neurological drugs, particularly Levodopa-associating treatment. Our research also revealed that the administration of non-pharmacological treatment and changes made in chronic neurological treatment explain the favorable response to orthostatic tolerance test at discharge when compared with admission.

We suggest that he management of orthostatic hypotension in patients with Parkinson's disease should always start with patient education, identification and, if possible, a change of the potential hypotensive neurologic therapy.

UNMASKING A YOUNG ADULT MIGRATORY DEEP VENOUS THROMBOSIS – CASE REPORT (Abstract): Venous thromboembolism is a known complication of cancer which impacts on patient mortality and quality of life. The primary site of cancer is an important risk factor, with highest rates observed in patients with brain, pancreas, gastric, kidney, ovary and lung cancers. The extent of metastatic spread further adds to the risk. In this article, we present the case of a young patient who was diagnosed with an aggressive form of pancreatic neoplasm with secondary determinations, without any previous digestive symptoms, with the occasion of a recurrent and migratory deep venous thrombosis (DVT). **Keywords**: CANCER, PANCREAS, DEEP VENOUS THROMBOSIS, RECURRENT.

Deep venous thrombosis (DVT) and pulmonary embolism (PE) are major causes of morbidity and mortality (1). Several patient's characteristics are associated with a higher incidence of venous thromboembolism (VTE) and include, among others (2), age greater than 65 years, female gender, obesity, immobility, major surgery and infection (3,4). The risk of VTE may also substantially be increased by heritable prothrombotic states such as factor V Leiden or prothrombin gene mutation or acquired conditions (e.g. antiphospholipid antibodies), in addition to a prior VTE. Cancer patients are known to be at increased risk of VTE. The primary site of cancer is an important risk factor for VTE, with highest rates observed in patients with brain, pancreas, gastric, kidney, ovary and lung cancers. The extent of metastatic spread further adds to the risk (5, 6).

We present the case of a young patient with recurrent and migratory DVT, who was diagnosed with an aggressive form of pancreatic neoplasm with secondary determinations, without any previous digestive symptoms.

CASE PRESENTATION

A 42 year old man, from an urban area, was admitted to our department, in October 2012 for swelling of legs, local pain, heat

and redness, irritability, fatigue. The patient was a smoker for twenty years ago, and denied alcohol consumption. In August 2012, he was diagnosed with DVT of the left leg, and with two weeks before current admission in the hospital he was diagnosed with DVT on the right femuro–popliteal axis and superficial phlebitis of the right leg, being under treatment with Acenocumarol 4 mg per day, Diosminum 500 mg 2 tablets per day and Sulodexidum 250 ULS 2 tablets per day. The patient declared loss in body weight, approximately 4 kg in the last two months.

Physical examination showed pale skins and mucosa, normal state of nutrition (BMI 23.6 kg/m^2), arterial blood pressure 125/80 mmHg, heart rate 69/min, respiratory frequency 16/min. Clinical examination did not reveal any tenderness of the abdomen, liver and spleen were not palpable. Local clinical exam revealed edema, redness and heat of both legs.

Laboratory tests at admission showed leucocytosis (12,700/mm^3) and neutrophilia (66.5% - 9,500/mm^3), mild normochromic, normocytic anemia (Hb 12.9g/dl), dyslipoproteinemia, very increased C reactive protein (12.71 mg/dl), hyperglycemia (187 mg/dl), therapeutic hypocoagulability (INR 2.39), absence of fibrin degradation products (FDP) and increased D-dymers (21.7 μg/ml). Liver function tests revealed mild hepatocytolysis (ASAT 47 U/l, ALAT 74 U/l), cholestasis (total bilirubin 1.43 mg/dl, conjugated bilirubin 0.73 mg/dl, alkaline phosphatase 617 IU/l, GGT 751 IU/l), and normal total serum proteins. The platelet count, blood urea, creatinine, sodium and potassium, alkaline reserve, uric acid level, urinary examinations were within normal range.

The abdominal ultrasound examination revealed increased volume of liver, nodular structure, unhomogeneously overall, and presence of a small quantity of right pleural fluid, which was also confirmed radiological. The cardiac ultrasound exam evidenced normal systolic and diastolic function of left ventricle, atherosclerotic ascending aorta.

Doppler venous ultrasound revealed, on the right leg, an 8.5 mm thickness thrombus in the deep femoral vein at third inferior thigh and subcutaneous edema, absence of Doppler signal in the popliteal and posterior tibial veins, peroneal and saphenous vein until middle third of the thigh. On the left leg, in the third inferior thigh, there was detected a thrombus of 8.4 mm thickness, with partial recanalization, incompressibility and absence of Doppler signal on the posterior tibial vein, saphenous vein and veins from the posterior side of the calf.

Considering the recurrent and migratory character of DVT in a young patient, we examined the thrombophilic state, by testing possible deficiences of antithrombin III, protein C and S, factor V Leiden and prothrombin gene mutations, lupic anticoagulant, antiphospholipid antibodies and MTHFR genes (mutations C677T and A1298C). All of these tests were within the normal range. Also for thrombotic state under chronic oral anticoagulation (with therapeutic INR), taking in consideration the young age, absence of risk factors (obesity, hip or lower limb fractures, immobility, major surgery or trauma, infection), we determined the tumor markers, which revealed increased carcinoembryonic antigen (CEA - 37.7 ng/ml) and very increased level of tumoral antigen CA 19-9 (>1000 IU/ml), with normal levels of prostate specific antigen and alpha-feto-protein.

In this stage, regarding the markedly changes in tumor markers, inflammatory tests and the ultrasound aspect of the liver, we considered compulsory an abdominal computer tomography (CT) examination, which revealed a solid and expansive tumor of pancreatic body and tail, imprecise delimited, size of 46/57/45 mm, with decreased density compared to the rest of pancreatic parenchyma in arterial and venous time (fig.1), secondary liver determinations (fig.2), thrombosis of the left portal vein, splenic artery and vein (fig.3,4), probability of splenic infarctions. There was also detected tumoral lymphadenopathy placed around the pancreatic tumor, in mesenteric and celiac area, in the splenic hilum and on the small gastric curvature.

During hospitalization, which involved primary therapy with subcutaneously anticoagulant (sodium enoxaparine), then oral anticoagulant (acenocumarol), under INR control, diosminum and sulodexidum, analgesic and anxiolytic treatment, clinical and paraclinical evolution was slowly favorable, with reduction of the legs thrombotic signs (redness, pain and swelling) and without any gastrointestinal signs or symptoms.

Fig.1. The pancreatic tumor does not have demarcation limit by left adrenal gland (body) and by first ileal loop

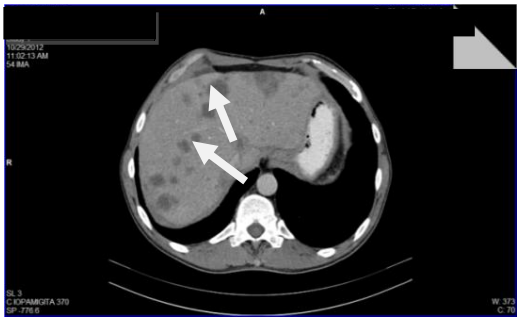

Fig. 2. Multiple hepatic solid lesions, with reduced vascularity, some with tendency to confluence, disseminated in both liver lobes

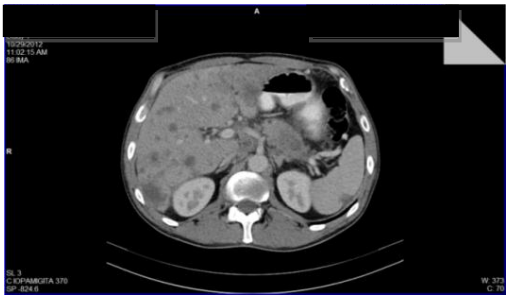

Fig.3. The splenic vene cannot be seen (completely obstruction)

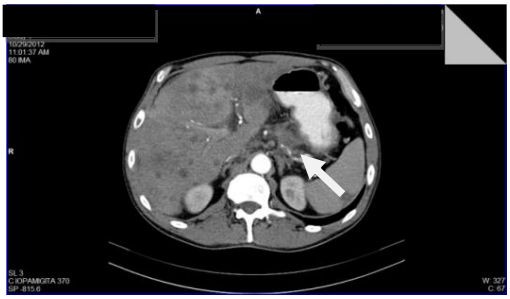

Fig.4. Spleen artery is permeable, with present blood flow on the first 6.5 mm, being obstructed at the level of the tumor

The patient was directed to the surgical department, where, because of the advanced stage of the neoplasm, was not operated, but received recommendations to

address to oncologic department. In oncology, the patient was subjected to two chemotherapy cures, with an unfavorable evolution, the death occurring at the end of November 2012.

We consider this is an interesting medical case, in which a migratory and recurrent DVT in a young patient discovered an aggressive form of pancreatic neoplasm, with hepatic secondary determinations, without any previously digestive symptoms and with a very fast unfavorable evolution.

DISCUSSION

It has been recognized that venous thromboembolic events are common in patients with cancer. Patients with cancer represent approximately 15-20% of all new cases of venous thromboembolism (4). Cancer is associated with about a 3-fold increased risk of recurrent VTE both during and after anticoagulant therapy, and among patients with cancer, the risk of recurrence is about 3-fold higher in those with metastatic disease (7).

Our patient, a relatively young man, developed recurrent and migratory DVT, without any digestive symptom, abdominal pains, loss of appetite, or disorders of bowel transit, but only with about 4 kg loss in body weight in the last two months. Because of recurrent and migratory character of DVT, taking in consideration that the patient didn't have any thrombotic risk factors (normal thrombophilic state, normal state of nutrition, absence of immobility, major surgery, fracture or infection), under chronic oral anticoagulation (with therapeutic INR), our thought was to investigate a possible malignant cause of thrombosis, starting with tumoral markers, which had significant changes (especially CEA and CA19-9) and abdominal CT. Abdominal CT revealed an advanced stage of pancreatic neoplasm (T4N1M1), with secondary liver determinations, disseminated tumoral lymphadenopathies and invasion of portal and splenic veins. The diagnostic of secondary diabetes mellitus by hyperglycemic level is related to the location of the tumor into the pancreatic body and tail. Also, inflammatory state (leukocytosis and increased CRP) are related to the tumor presence, and hepato-cytolysis and cholestasis are due to secondary liver determinations and invasion of portal vein.

Recent studies showed that VTE tends to be associated with advanced and aggressive forms of cancers, while average life expectancy is poor in this group of patients (40% mortality at 6 months after diagnosis of VTE) (8). While the risk of VTE by tumor type remains uncertain for the majority of cancers, the risk appears to be highest for patients with malignant brain tumors and cancer of the ovary, pancreas, and lung (6). Multiple and interdependent mechanisms are responsible for the hypercoagulability state in patients with cancer. Tumor procoagulant activity, host inflammatory responses and extrinsic factors, which are frequently iatrogenic, are involved. Furthermore, recent evidence has shown that tumor-induced coagulation activation is intrinsically involved in tumor cell growth, angiogenesis and metastasis (2).

In conclusion, admitting that there are cases of cancer associated with DVT, by this report we want to draw attention on the fact that, in a young patient with recurrent DVT, without any apparent risk factor for thrombosis, attention should be higher to check for a thrombophylic state or for an active malignancy, even in the absence of signs or symptoms of organ sufferance.

NEWS

PERIODONTAL STATUS OF PATIENT'S UNDERWENT HEMODIALYSIS THERAPY

The patients with chronic renal failure undergoing hemodialysis are susceptible to periodontal diseases due to systemic complications of the disease and using different drugs. A group of researchers from the Department of Periodontics of Babol University of Medical Sciences, Iran investigated the periodontal status of patient's who underwent hemodialysis. The study realized in Shahid Beheshti Hospital in Babol, Iran included one-hundred-fifteen hemodialysis patients (63 males and 52 females) with the mean age of 47.9±15.3 years. Periodontal parameters (plaque index, gingival index, clinical attachment level and probing pocket depth) were measured. The data were registered and analyzed. The plaque index, gingival index, clinical attachment level and probing pocket depth were 2.37±0.55, 2.36±0.63, 3.98±1.61 and 4.41±1.4, respectively. Significant positive correlations were found between the participants' age and plaque index ($p<0.024$) and $p<0.001$, respectively. Clinical attachment level was significantly higher in males (4.39±1.57) than females (3.53±1.56), $p<0.02$. The obtained data revealed that, especially in males, a longer duration of hemodialysis is associated with severe periodontal diseases. (Jenabian N, Ghazi Mirsaeed AM, Ehsani H, Kiakojori A. Periodontal status of patient's underwent hemodialysis therapy. *Caspian J Intern Med*, 2013; 4 (2):658-661).

NUTRITION IN INFLAMMATORY BOWEL DISEASES (Abstract): The relationship between nutrition and inflammatory bowel disease (IBD) is a complex one, the evaluation and correction of nutritional deficits being integral part of therapy in these patients. The diet that consists in excessive consumption of meat, sugar, fats (with a higher ω 6 /ω 3 polyunsaturated fatty acids ratio) are factors involved in the epidemiology and pathogenesis of IBD. Malnutrition is present among most IBD patients, being the result of multiple mechanisms from digestive symptoms to inflammatory process, intestinal resection and administration of medications. Oral diet is high-calorie, high protein at correcting the vitamin and mineral deficiencies. Enteral diet has both an adjuvant role and that of inducing and maintaining remission as single treatment, particularly in children. Parenteral nutrition is reserved for patients with obstruction, fistula, toxic megacolon, short bowel syndrome, severe malabsorption, and other conditions that make enteral nutrition impossible or inefficient. **Keywords**: NUTRITION, INFLAMMATORY BOWEL DISEASE, ENTERAL DIET.

Role of nutrition in IBD pathogenesis. The incidence of inflammatory bowel disease (IBD) has increased over the last decades, particularly in developed countries, countries that have adopted habits specific to other geographical areas (Japan, India), or in people that migrated to developed countries and took over new alimentary habits. This epidemiological trend is primarily accounted for by dietary change (1).

Increased consumption of sugars, fats, low-fiber or high raw diets may cause by the high content in titanium oxide, silica, etc. resistance to degradation, or by incorporation in Peyer plaques macrophages, exacerbation of inflammation in Crohn disease (CD) in genetically predisposed individuals. Excessive consumption of meat and alcohol favors relapse in ulcerative hemorrhagic recto colitis (UC) (the sulfur compounds in these foods intensifies the inflammatory process) (2).

Fats with higher ω 6/ω 3 polyunsaturated fatty acids (PUFA) ratio increase the incidence of CD. European studies have shown that higher linoleic acid levels are associated with increased risk for UC. If ω-3 PUFA have anti-inflammatory properties (fish oil rich in ω-3 PUFA decreases the production of inflammatory mediators interferon γ:, PGE 2), ω 6 PUFA (arachidonic acid, linoleic acid) have proinflammato-

ry properties (3, 4).

Prevalence of nutritional deficits in IBD. Malnutrition is represented by the discrepancy between body needs and food intake and its components, from macronutrients - carbohydrates, lipids, proteins - to micronutrients-vitamins, minerals.

Malnutrition is present in 85% of IBD patients, and weight loss in 80% of CD and 18-62% of UC cases. Growth deficiency, especially in CD, is not only due to inadequate calorie intake but rather to the inhibition of the growth factor due to elevated leves of proinflammatory cytokines. Deficiency in vitamins A, D, K, E promotes inflammation which is found in 40 to 90% of IBD patients, commonly without clinical signs and without any decrease in the nutritional intake (5, 6).

Nutritional status. A single indicator is not enough to determine the nutritional status, its assessment requiring nutritional history, physical examination and laboratory data (5, 6). Subjective global assessment, originally used in oncology, could be a tool for the screening of IBD patients (using the following parameters: history of weight loss, food intake, gastrointestinal symptoms, functional capacity) (7) (tab I).

TABLE I.
Subjective global assessment in IBD patients

Criteria	Adequate nutrition	Moderate malnutrition	Ssevere malnutrition
Unintentional weight loss (last 6 months)	loss < 5%	5 - 10%	> 10 %
Diet	to the needs	70 - 90 % of the needs	< 70 %
Gastrointestinal symptoms (anorexia, nausea, vomiting, shortness of breath, change in taste)	absent	intermittent	daily
Functional capacity	normal	reduced	
Disease type	remission	moderate	severe

Serum levels of albumin may be used as a marker of nutritional status. Hypoalbuminemia occurs in 25-80% of CD patients and 25-50% of those with UC and reflects the metabolic response to stress, so that in IBD its level can be normalized by proper nutrition and by the correction of inflammatory process (8).

Etiopathogenesis of malnutrition in IBD. There are multiple causes and mechanisms that explain the occurrence of malnutrition in IBD. Decreased food intake is due to anorexia, nausea, vomiting, abdominal pain and diarrhea, as well as to restrictive diets. In explaining anorexia in IBD, an important role is played by pro-inflammatory cytokines: TNF-alpha, IL 1β, IL -6, leptin, produced by the activation of monocytes, macrophages, lymphocytes to various stimuli that cause disturbances in the use and absorption of proteins, carbo-

hydrates, lipids (9).

Maldigestion occurs in (10):

- sclerosing cholangitis which is characterized by the decrease of bile secretion decreases with slow digestion and absorption of fats and fat-soluble vitamins;
- blind loop syndrome (small bowel bacterial overgrowth) causes fat maldigestion as a result of bile salts deconjugation by bacteria;
- overgrowth of small bowel intestinal flora causes progressive mucosal alteration together with the destruction of mucosal disaccharides by inflammation, leading to carbohydrate maldigestion, osmotic diarrhea and flatulence.

Malabsorption is secondary to extensive intestinal inflammatory process, intestinal resections that cause a decrease in absorption surface, microbial overpopulation (blind loop syndrome) that causes bile acid and vitamin B_{12} malabsorption (11).

Fever and infection (sometimes septic) increase the caloric needs, resulting in weight loss.

Another mechanism is the increased losses as a result of inflammation and proteins and fluids transudation through altered mucosa: mucosal bleeding often causes anemia; fistula result in loss of Zinc, electrolytes, fluids, non-absorbable fats bind luminal Calcium (Ca) and Magnesium (Mg) and causing decreases in Ca and Mg levels (12).

Medications may also represent potential sources of malnutrition (13): Sulfasalazine decreases the absorption of folic acid and dihydrofolate reductase activity; Corticosteroids inhibit Ca absorption and increase urinary Mg level; Antibiotics induce the decrease of vitamin K; Cholestyramine binds bile acids and affects the metabolism of fat soluble vitamins.

Nutrition in the treatment of IBD. It is a supportive therapy by correcting specific nutritional deficits determining the induction and maintaining remission.

Oral nutrition. Its particularities will be established following a dietitian advice for a healthy, individualized diet with an elementary, fractioned intake with liquid oral supplements. Compliance with elemental or semi-elementale diets in CD and acute UC episode is poor due to their cost, taste, smell, texture (14, 15).

Resting energy requirements are not increased in CD patients and BMI can be used to assess the caloric needs. The energy requirements of IBD patients are strictly dependant of the BMI (13) (tab. II).

TABLE II.

Energy requirements of IBD patients according to BMI

BMI (kg/m^2)	Energy requirement (kcal/kg body weight)
< 15	36 - 45
15 - 19	31 - 35
20 - 29	26 - 30
> 30	15 - 25

Proteins. Patients with IBD have increased protein needs due to intestinal losses and increased catabolism (infection/abscess/required surgery). Protein needs are assessed by body weight and disease status. The recommended daily protein intake for IBD patients without kidney disease is 1-1.5 g/kg, being reduced to 0.8 g / kg body weight for the patients with renal failure not receiving dialysis (15).

Vitamins and minerals. (10) (tab. III).

TABLE III
Vitamin and mineral requirements and treatment of deficiencies in IBD patients

Nutrient	Recommended daily requirements	Signs and symptoms of deficiency	Recommended replacement oral dose
Zinc	15 mg	Dry, flaky skin, palm peeling, diarrhea, mental status changes	50 mg elemental/day
Iron	10 -15 mg	Microcytic anemia, fatigue	300 mg 1-3/day
B_{12} (cobalamin)	3 mcg	Megaloblastic anemia, parenthesis, ataxia, diarrhea, mental status changes	1000 mcg/day
Folate	400 mcg	Sore mouth, glossitis, diarrhea, inattentiveness, megaloblastic anemia	1 mg/day
Calcium	800 - 1500 mg	Osteopenia, osteoporosis, tetany	1500 - 2000 mg/day
Magnezium	400 mg	Nausea, muscle weakness, arrhythmia, confusion, convulsions	150 mg elemental Mg 4x/day
Vitamin D	400 UI	Rickets, osteomalacia, bone pains, muscle weakness, tetany	variable

Vitamin B_{12} deficiency is found in distal ileal CD or in case of gastric resection (intrinsic factor deficiency) or terminal ileum (absorption deficit). Due to these aspects serum methylmalonic acid (S-MMA) concentration is elevated, vitamin B_{12} concentration is decreased, and homocysteine is elevated (influenced by vitamin B_6 and folate status). B_{12} deficiency stages are (16): I, II – plasma and brain stores are depleted; III – elevated levels of S-MMA and homocysteine, with clinical signs starting to occur; IV - macrocytosis with increased mean corpuscular volume (MCV).

The treatment consists in the administration of vitamin B12: i.m ampoule = 1000 μg 1 ampoule/month, intranasal 500μg x 4/month. p.o cp = 1000 μg, 30 cp/month.

Folic acid deficiency occurs either through increased requirements (methotrexate is a folic acid antagonist and sulfasalazine blocks the absorption of folic acid) or by decreased intake (the main sources of folic acid - fruits, vegetables - are difficult to tolerate for IBD patients). Supplementation with folic acid 1 mg/day corrects the deficiency and protects against the risk for colorectal cancer. A special mention must be made on increased homocysteine levels that occur in vitamin B_{12} and folate deficiency, with increased risk for thrombosis, atherosclerosis, cardiovascular diseases, stroke (17).

Calcium and vitamin D deficiency. Bone metabolism disorders increase by 40% the risk of fractures in IBD. DEXA scan (dual energy X-ray absorptiometry) evaluates osteoporosis diagnosis and the therapeutical programme. The prevalence of osteoporosis is evaluated at 3-58% in UC and 4-50% in CD, due to deficiencies in proteins, vitamin D, and Ca intake, presence

of inflammatory cytokines and corticosteroids. A major role is represented by old age, weight loss, disease status, and treatment with corticosteroids. Supplementation with Ca + vitamin D preparations (1000-15000 mg Ca + vitamin D 400-600 IU / day) is recommended and taking into consideration the fact that Prednisone can induce vitamin D resistance by increasing parathyroid hormone level and calcium losses. In patients with severe malabsorption 2,000-4,000 IU of vitamin D/day need to be administered parenterally, and in osteoporosis, bisphosphonates are preferred (18, 19).

Mineral deficiency. *Zinc deficiency* occurs in fistulas and short bowel syndrome. The recommended dose for substitution is 15 µg/ kg/day. *Iron deficiency* secondary to hemorrhage occurs in 80% of UC patients and in 40% of those with colonic CD. In iron deficiency anemia injectable iron (100-200 mg ferrous sulfate) is preferred because iron administered p.o is accompanied by gastrointestinal intolerance in 21% of cases, and intestinal inflammation and increased risk for colorectal cancer. *Magnesium deficiency* occurs in case of fistulas and colectomies, and short bowel syndrome and parenteral administration is preferred: 5% magnesium gluconate which has a high solubility (10).

Enteral nutrition (EN) in IBD, used since the 70's and 80's, may be used as therapy or as adjuvant to drug therapy. Studies on EN showed several characteristic aspects for patients with CD (20.21): corticosteroid therapy is more effective in obtaining remission compared to EN in adults; EN in children, particularly ileum located, is superior to corticosteroid therapy, being the choice of first-line treatment for reducing the negative effects of corticosteroids on growth and bone metabolism; No difference was observed between the three enteral nutrition formulas: elemental (nitrogen in the form of free amino acids); oligomeric (nitrogen in the form of peptides or protein hydrolyzates); polymeric (nitrogen in the form of whole proteins).

The studies on EN in UC have shown inconsistent results, most of them not recommending it either in inducing or maintaining remission.

Enteral therapy is not a standardized therapy throughout the world with differences in Europe, America, Canada, and Japan. According to the ESPEN Guidelines on Enteral Nutrition (2006), the general goals of enteral nutrition are: prevention and treatment of subnutrition, improvement of weight growth and development in children and adolescents, and a better quality of life. For adults with active forms of disease EN is indicated as sole therapy if the patient refuses or has contraindications to corticosteroids (22).

Combined therapy is indicated perioperatively in malnourished patients with intestinal stenosis (weight loss > 10%, BMI <18.5, and albumin below 30 g/l). The response to enteral nutrition is assessed after 3 to 6 weeks (23).

EN diminishes inflammation and induces remission without the side effects of 5-amino-salicilyc derivates (5 ASA), steroids, or Azathioprine (AZA). It also has a role in maintaining remission, especially in patients with EN-induced remission. It also can cause "mucosal healing" through its local immunstimulatory action (24).

The disadvantages of EN are related to its high costs, not covered by insurance, lack of compliance to prolonged administration (4-8 weeks), absence of generally accepted protocols, medical skepticism, and last but

not least the administration route.

Enteral nutrition is administered orally, by nasogastric or nasoenteric tubes. If EN should be administered for more than 4 weeks, a percutaneous gastrostomy or jejunostomy is required (in CD patients this procedure increases the risk for fistulas). The main complications are: aspiration, hemorrhage, perforation, nose bleeding, pneumothorax, tube obstruction, intestinal ischemia and in stoma there is a high risk of infections, fissures or ulcerations (22).

Parenteral nutrition. Parenteral nutrition (PN) is indicated in the following situations: obstruction, fistula, toxic megacolon, short bowel syndrome, severe malabsorption, loss of fluids and electrolytes, other conditions that make EN impossible/ineffective. Crohn's disease is one of the main indications for PN at home (20% of patients on PN have CD). The most common complications of PN can be: liver, biliary, catheter sepsis, thrombosis, decreased quality of life (25).

Nutrition in IBD complications

Fistulas in CD are due to Zinc, electrolyte and fluid losses that require nutritional correction. PN is used, or when fistula flow is less than 1500 ml/24 hours, EN can be used. There are studies in the literature on small series of adult patients showing that PN as sole therapy may delay or avoid surgery. The data available so far do not support the possibility of fistula closure solely by digestive rest.

In ***stenoses*** nutrition depends on stenosis length and type (inflammatory *vs.* fibrous). When oral nutrition is possible the diet should be low in dietary fibers and hard to chew foods to prevent obstruction. Tight, fibrous stenoses may require EN or PN prior to surgery.

In ***toxic megacolon*** EN or PN is an adjuvant to drug therapy. A randomized study on 42 patients with UC - fulminant form – which received corticosteroid therapy associated with EN *vs*. PN - demonstrated the superiority of EN (the number of colectomies was identical for arms, but the side effects, postoperative complications, and albumin levels were in favor of EN).

In IBD patients requiring ***surgery***, PN is administered perioperatively. A preoperatively adequate nutritional status decreases the risk of postoperative complications and IBD recurrence. Nutritional therapy is indicated in patients who lost more than 10% of their weight in the last 3-6 months, have a body mass index <18.5 kg/m^2 or hypoalbuminemia (albumin <30 g/l). NP should be administered postoperatively until patients resume enteral or oral nutrition as in the case of the other abdominal surgeries (26).

Short bowel syndrome (SBS) is a malabsorption disorder secondary to extended bowel resection (in adults less than 200 cm remaining intestine). There are three stages of disease progression (27): Phase 1, lasting up to several weeks, is characterized by massive loss of fluids and electrolytes; Phase 2, adaptation phase (lasting approximately 2 years) is characterized by anatomical changes (increase in villus height and enterocyte number) and functional changes (changes in permeabiity and transmembrane transporters); Phase 3 is that of maintenance.

Long term PN is indicated in all cases with jejunocolic anastomosis and less than 50 cm jejunum remaining and in those with colectomy and less than 100 cm residual small bowel. Given the complica-

tions and difficulties of long-term PN, the return to oral or enteral nutrition is attempted through: improve oral and liquid diets, micronutrient supplementation, use of trophic factors, antisecretory and antidiarrheal drugs, and antibiotics (to treat bacterial overpopulation syndrome). In case of failure, small bowel transplantation should be considered.

Oral rehydration solutions should contain glucose and electrolytes (Na>90 mmol/l). Hyperosmolar solutions (e.g. fruit juices) will not be administered. The diet aims to increase energy intake by 50% (by repeated small meals) in association or not with EN (preferably a polymeric or semi-elemental formula administered through nocturnal gastric tube). It should consists of: 50-60% complex carbohydrates (which reduce osmotic load), 20-30% fat (long- and medium-chain triglycerides), and 20-30% protein (meat, fish). Supplementation with soluble fibers delays gastric emptying and increase intestinal adaptation. Oxalate-rich foods (cola, tea, coffee, draft beer, cherry, orange, lemon, red cabbage, saffron, French fries, etc.) should be restricted due to the increased risk for oxalate nephropathy (which occurs in 25% of SBS patients due to the inability to eliminate oxalates because fatty acids bind calcium) (28).

As to micronutrient supplementation the following should be administered: vitamin A (5,000 to 30,000 IU/day i.m. or p.o.); vitamin B_{12} (300-1.000 mg/month s.c. or i.m.); vitamin C (250-500 mg/day p.o.); vitamin D (800–1.600 IU/day p.o. or i.m.); vitamin E (400 U 3x/day p.o.); folate (1 mg /day p.o.); iron (325 mg x 3/day p.o.); zinc (50 mg elemental Zn - 220 mg tablet, 1-2 x/day); selenium (100 mg/day p.o.); calcium (1500-2000 mg/day p.o.); potassium (20 - 80 mEq/day); magnesium (magnesium oxide 12-24 mEq/day - will be given parenterally or nocturnally not to aggravate diarrhea (29).

Encouraging results in studies on animal models were obtained with intestinal mucosal growth factors: growth hormone (GH) (approved by the Food and Drug Administration-FDA in the treatment of short bowel syndrome), glucagon-like peptide 2 (GLP-2), glutamine, peptide YY analog. In humans, however, the results are controversial, so these factors cannot yet be recommended in clinical practice (27).

In **conclusion,** nutrition in IBD is a complex problem that requires a good nutritionist - gastroenterologist collaboration and patients with IBD will benefit by the assessment and correction of existing deficits. Enteral nutrition is an adjuvant therapy in inducing and maintaining clinical remission and in mucosal healing.

Parenteral nutrition is reserved for severe cases with complications.

PERIPARTUM CARDIOMYOPATHY: A CHALLENGE FOR CARDIOLOGIST (Abstract): Peripartum cardiomyopathy (PPCM) is a rare but potentially life-threatening condition that occurs in previously healthy women during the last month of pregnancy and up to 5-6 months postpartum. The etiology and pathophysiology remain uncertain, although recent observations strongly suggest the specific role of prolactin cleavage secondary to unbalanced peri/postpartum oxidative stress. PPCM is a diagnosis of exclusion, as it shares many clinical characteristics with other forms of systolic heart failure secondary to cardiomyopathy. The management of heart failure requires a multidisciplinary approach during pregnancy, considering the possible adverse effects on the fetus. After delivery, the treatment is in accordance with the current guidelines for heart failure. Some novel therapies, such as prolactin blockade, are proposed to either prevent or treat the patients with PPCM. A critical individual counseling concerning the risks of subsequent pregnancy must be considered. Because of its rare incidence, geographical differences, and heterogeneous presentation, PPCM continues to be incompletely characterized and understood. For all these reasons, PPCM remains a challenge in clinical practice, so future epidemiological trials and national registries are needed to learn more about the disease. **Keywords**: PERIPARTUM CARDIOMYOPATHY, PROLACTIN, ECHOCARDIOGRAPHY, BROMOCRIPTINE, RIK OF RELAPSE.

DEFINITION, EPIDEMIOLOGY

In 1849, Ritchie was the first to establish a relationship between heart failure and puerperium. However, peripartum cardiomyopathy (PPCM) was recognized as a distinctive form of cardiomyopathy in 1937, when Gouley (cit. 1) described the clinical and pathological features of a severe heart failure associated with a dilated cardiomyopathy in the later months of pregnancy persisting after delivery. In 1965, Walsh (cit. 1) was the first to propose the specific period for the diagnosis, and highlighted that other conditions must be excluded. In 1971, Demakis et al. (2) defined the condition PPCM. The investigators established the original diagnostic criteria, which were subsequently confirmed by the National Heart Lung and Blood Institute [NHLBI] and the Office of Rare Diseases of the National Institutes of Health [NIH] Workshop, and completed with an echocardiographic criterion (3) (tab. I).

In 2010, Heart Failure Association of the ESC Working Group on PPCM proposed a new definition: "an idiopathic car-

diomyopathy presenting with heart failure secondary to LV systolic dysfunction towards the end of pregnancy or in the months following delivery, where no other cause of heart failure is found. It is a diagnosis of exclusion. The LV may not be dilated but the ejection fraction is nearly always reduced below 45%“ (1).

TABLE I

Original definition of peripartum cardiomyopathy

Classic criteria (Demakis et al.) (2)
1. The development of heart failure in the last month of pregnancy or within the first 5 months postpartum
2. The absence of an identifiable cause for heart failure
3. The absence of recognizable heart disease prior to the last month of pregnancy
Additional criterion (NHLBI & the Office of Rare Disease of NIH) (3)
4. Left ventricular systolic dysfunction demonstrated by classic echocardiographic criteria (depressed ejection fraction or shortening fraction)

Although the condition has been defined by several confusing names, PPCM is the preferred term because it highlights the overall chronological spectrum of the disease (4). Another accepted term is pregnancy-associated cardiomyopathy or early peripartum cardiomyopathy, used for those females with cardiomyopathy developing heart failure before the last month of pregnancy or at least five months after delivery (5).

Good data about incidence are unavailable because so few population-based registries exist. Until recently, only small prospective studies were available to estimate the incidence of the disease (5-8). Only two large retrospective population-based studies have been conducted in USA with a reported incidence ranging between 1:3189 live births and 1:4025 live births (9, 10). The estimates are almost similar for Japan and Australia. PPCM is sporadic in Europe in the white women (11,12). The more recent data from the United States suggest the highest incidence in African-Americans (10). Outside the United States, the most comprehensive data came from the Peripartum Cardiomyopathy Project in Haiti, which estimated the incidence of PPCM as high as 1case/299 live births (7). The data have been confirmed by Gentry (13), who noted an incidence of 1 case/1000 live births in South Africa. Although not clearly delineated, there are several suggested risk factors for the development and recurrence of PPCM (2, 3, 11, 14-19):

- african race appears to be the strongest risk factor;
- advanced maternal age – the disease generally occurs over the age of 30 years;
- multiparity – 71% of cases occur after ≥ 3 pregnancies compared with 8% in primigravidas;
- twin pregnancies in 8-13% of cases compared with 1-2% rate noted among healthy women;
- gestational hypertension in 43% of cases, substantially higher than the 8% to 10% incidence in the overall pregnant population;
- the unique association with prolonged use of tocolytics for a period of at least four weeks;

- certain cultural practices such as consuming lake salt or rock salt known as "kanwa" or heating of the body on a clay bed with a fire beneath to keep warm;

- socio-economic level summarized in a stereotyped profile: "poor African female, with malnutrition and multiparity, making strenuous and sustained physical effort during pregnancy".

ETIOLOGY AND PATHOGENESIS

Despite extensive research into its underlying etiology and pathogenesis, it is not clear exactly how PPCM occurs (17). The pathogenetic mechanisms of PPCM have been difficult to study as its incidence is too low to allow meaningful evaluations, and the suitable animal models to study the disease are rare. Several putative hypotheses, such as abnormal immune response to pregnancy, citokine-mediated inflammation, increased myocyte apoptosis, abnormal response to hemodynamic stress, genetic susceptibility, malnutrition, increased adrenergic or vascular disease have been proposed, but, at the present time, two hypotheses are foremost: pregnancy associated hormonal changes, specifically the role of prolactin, and viral infection.

Pregnancy is a physiological state associated with enhanced oxidative stress. In order to protect the heart, an efficient antioxidant defense mechanism counteracts the oxidative stress. The total antioxidant capacity increases in the last trimester with a peak in early postpartum (20). STAT3 is a cardiac tissue-specific DNA-binding protein which protects the heart from pregnancy-induced oxidative stress (21). The protein pathway is activated by full-length 23-kDa prolactin, a hormone with no adverse effects on the heart. Reduced levels of STAT3 lead to an unbalanced peri/postpartum oxidative stress, a potent stimulus for the activation of prolactin-cleaving protease catehpsin D in cardiomyocytes. The result is cleavage of the nursing hormone prolactin into an antiangiogenic, proapoptotic and proinflammatory 16-kDa subfragment, which also promotes ventricular dilatation and reducing of cardiac function. The same fragment inhibits vascular endothelial growth factor-induced proliferation of endothelial cells and migration, induces apoptosis, dissociation of capillary structures, impairs nitric oxide-mediated vasorelaxation, and cardiomyocyte function (22,23). In explanted terminally failing hearts from PPCM patients, low STAT3 protein levels are displayed, suggesting the role of this signaling pathway in the pathogenesis (22). Prolactin production is not limited to pituitary gland, various other cell types, such as fibroblasts, being able to produce it. PPCM is often associated with a high degree of cardiac fibrosis mediated by locally produced prolactin, which enhances the circulating pituitary 16-kDa prolactin damaging cardiac effects. There is more evidence linking findings from experimental models to human PPCM. Patients with acute PPCM have increased serum levels of oxidized low-density lipoprotein and significantly elevated pro-apoptotic serum markers (e.g. soluble death receptor sFas/Apo-1), indicative for enhanced oxidative stress, activated cathepsin D, and 16-kDa prolactin compared with pregnancy matched healthy controls (24). Consistent with the idea of prolactin involvement, blockade by bromocriptine, a dopamine D2 receptor agonist, was tested. Bromocriptine eliminates the substrate for the generation of 16-kDa prolactin, and prevents the onset of disease in the mouse model of PPCM (22) (fig. 1).

Several reports suggest that bromocriptine may have beneficial effects when added to the standard therapy of heart failure in women with acute onset of PPCM (25,26).

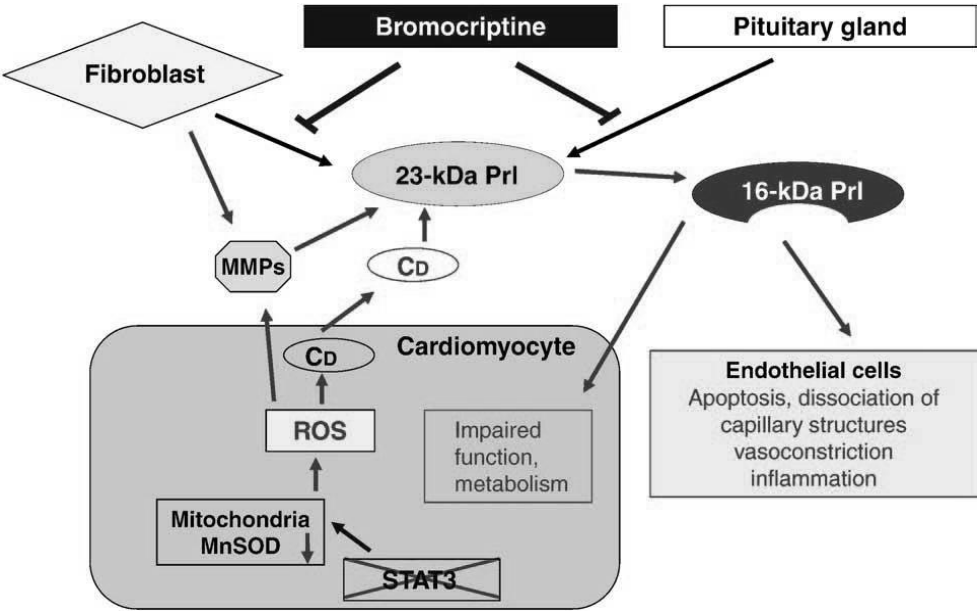

Fig. 1. Schematic mechanism for the development of PPCM (adapted from 24)

Myocarditis as a cause of PPCM in humans was first suggested by Gouley (cit. 1) in 1937. Since then, several investigators have supported this hypotheses. On the other hand, the prevalence of viruses detected in endomyocardial biopsies ranges from less than 10% to 78%, with a similar incidence in controls, suggesting no specific role for viral infection. It is worth noting that the molecular pathological study of endomyocardial biopsies found a high prevalence of viral genomes (parvovirus B19, human cytomegalovirus and herpes virus 6, Epstein-Barr virus) as well as inflammatory changes consistent with myocarditis (30.7%) (28). Another investigation suggests that viral infection increases the severity of myocardial damage in postpartum mice in comparison with nonpregnant control subjects (12). It is possible that the postviral immune response to be directed inappropriately against native cardiac tissue proteins leading to LV systolic dysfunction in the presence of the characteristic hemodynamic changes during pregnancy. Given the imunosuppressed state of pregnancy, it is logical that pregnant women are more susceptible to infection or viral reactivation (3). At the present time, no convincing data exist that myocarditis is the primary etiology of PPCM. Further studies using newer technologies such as PCR are needed to confirm a pathogenic role (17).

DIAGNOSIS OF PERIPARTUM CARDIOMYOPATHY

Patients with PPCM present with classical signs and symptoms of systolic heart failure due to other cardiomyopathies (28).

NYHA class III or IV functional status seems to be the most common initial presentation (6). Some case series describe unusual presentations such as acute cyanosis, multiple thromboembolic events or liver failure (16,28). A latent form of PPCM without overt clinical symptoms has been reported (29). The clinical diagnosis still represents a challenge because symptoms of early heart failure can appear in normal late pregnancy and after delivery. The diagnosis should be considered whenever women experience unexplained heart failure during the last month of pregnancy or within 5 months following delivery. It is important to note that 78% of PPCM cases develop heart failure symptoms in the first 4 months after delivery (30). Interestingly, Fett (31) reported clinically normal postpartum in women with asymptomatic echocardiographic systolic dysfunction, who either developed dilated cardiomyopathy or completely recovered LV function. These cases may represent a latent phase of PPCM before the development of dilated cardiomyopathy later in life or subclinical dilated cardiomyopathy presenting in early pregnancy or a viral myocarditis, distinct conditions from true PPCM. The rapid onset of heart failure symptoms in the peripartum period is another clue for diagnosis. Very recently, Fett (32) proposed a screening tool for early diagnosis (tab. II). A score ≥ 5 has always been associated with LV systolic dysfunction. A score > 4 suggests the need for further investigation, such as BNP and echocardiography. If the score is < 4 the patient should be monitored for BNP and C-reactive protein levels. If increased levels, echocardiography should be performed.

TABLE II

Self-test for early diagnosis of heart failure in PPCM

Signs/Symptoms	**Characteristics**	**Scoring**
Orthopnea (difficulty breathing when lying flat)	None Need to elevate head Need to elevate $\geq 45^0$	0 1 2
Dyspnea (shortness of breath on exertion)	None Climbing 8 or more steps Walking on level	0 1 2
Unexplained cough	None At night Day and night	0 1 2
Swelling lower extremities	None Below knee Above and below knee	0 1 2
Excessive weight gain (during last month of pregnancy)	< 2 pounds/week 2-4 pounds/week > 4 pounds per week	0 1 2
Palpitations (sensation of irregular heart beats)	None When lying down at night Day and night, any position	0 1 2

The diagnostic work-up should focus on precise echocardiographic identification of new LV systolic dysfunction, peptide natriuretic measurement (3, 15), and ruling out other causes of heart failure. Additional investigations should be based on clinical suspicion. Blood tests, electrocardiogram, chest X-ray should be done in all patients, although none of these can help in screening or positive diagnosis. Echocardiography is the most widely used imaging method, which provides valuable, reproducible diagnostic and prognostic information. The technique is important to exclude other causes of heart failure and to monitor the evolution under treatment (1). In PPCM, cardiac MRI can be helpful at initial presentation to conduct further etiologic investigations (34). The interest for the technique is suggested by the ability to differentiate PPCM from other forms of cardiomyopathy, like Tako-Tsubo or ischemic cardiomyopathy. The technique might be a useful method for guiding biopsy to the abnormal area (35) and for prognostic stratification (36). Fett (37) supports cardiac MRI for guiding the immunosuppressive therapy in the inflammatory forms of PPCM, as this option of treatment has successfully been tested in "myocarditis-like" PPCM. The Heart Failure Association of the ESSC Working Group on PPCM (1) recommends cardiac MRI to be performed at 6 and 12 months for a better assessment of cardiac functional changes. PPCM remains a diagnosis of exclusion. Early detection is critically important to the patient with PPCM, because delayed diagnosis may be associated with increased morbidity and mortality (18, 33).

MANAGEMENT OF PERIPARTUM CARDIOMYOPATHY

When considering treatment during the peripartum period, a multidisciplinary approach is needed. Involvement of a cardiologist, obstetrician, anesthetist, intensivist, and neonatologist is imperative as earliest as possible after the diagnosis. The medical treatment is generally similar to that for other forms of non-ischemic dilated cardiomyopathy, with some general exceptions because of the risks of certain drugs on the fetus and newborn. The aims of medical treatment should be to reduce cardiac afterload and preload, while increasing myocardial contractility, to prevent complications, particularly thromboembolism, cardiac arrhythmia, progressive heart failure, and to improve long-term prognosis. Current therapeutic options consist of conventional supportive treatment for acute and chronic heart failure (38). Novel therapies are emerging, but the available data are inconsistent and limited. Some studies suggested that immunosuppressive drugs might be helpful in patients with active biopsy proven lymphocytic myocarditis, only after active viral infection is excluded (1). At present time, the role of immunosuppressive therapy in women with negative biopsies remains unknown. It is important to note that current therapies with ACEI, ARB and β blockers may have an additional effect on controlling the overactive immune system in PPCM. Also, immunomodulatory therapy acting on inflammatory cytokine TNF-α may be beneficial. Pentoxifyline, a xanthine agent known to inhibit the production of TNF-α and to prevent apoptosis, has been studied in PPCM. Sliwa et al. (39) reported a significant improvement of LV function > 10%, and end-diastolic dimensions, a reduction in mortality rate, and greater increase in functional status. Considering the observations that strongly suggest prolactin

cleavage as a specific mechanism for the development of PPCM, specific inhibition of its secretion with bromocriptine is promising. Several case reports demonstrated recovery of LV function after treatment with bromocriptine (25,40,41). Very recently, Sliwa (42) reported the results of a prospective, single-center, randomized, proof-of-concept pilot study of women with newly diagnosed PPCM receiving standard therapy with or without bromocriptine for 8 weeks. The addition of bromocriptine appeared to significantly improve LV function (27% at baseline, to 58% at 6 months). Analyzing these data together, Fett (43) remarked that important details of studies design must be corrected for appropriate results. Also, Fett suggests that bromocriptine treatment should be limited to those patients with LV ejection fraction < 35%, because of poor prognosis with standard therapy in this category. At the present time, a large prospective, multicenter, randomized trial is needed to allow bromocriptine extensive use. Such a trial is on-going in Haiti and South Africa (5).

In addition to the treatment of heart failure, an obstetrical plan for close monitoring must be developed when PPCM is diagnosed during pregnancy. A collaborative approach is essential to optimal care. Serial clinical assessments should be scheduled during late pregnancy. Antenatal testing, such as non-stress test and amniotic fluid index, or biophysical profile, baseline ultrasound scan for fetus is also recommended (44). Spontaneous vaginal delivery is preferred in stable women with healthy fetus. For patients with newly diagnosed PPCM before delivery, labor should be induced, or a cesarean section must be planned if mothers are critically ill (15). Breastfeeding should be avoided in PCCM, although several drugs have been tested and are safe.

PROGNOSIS AND PREGNANCY OUTCOME

Very few studies have been done to assess the long-term survival and recovery outcomes in PPCM. Although PPCM is a form of dilated cardiomyopathy, a characteristic feature is that a higher rate of spontaneous recovery of LV function occurs. However, a subset of women, despite using an optimal medical treatment, follows a rapid and irreversible course, associated with persistent LV dysfunction, severe heart failure, or premature death. Analyzing the long-term prognosis, Duran (45) concluded that NYHA functional class, QRS duration, and LV parameters at the time of diagnosis were important predictors. Initial cut-off values of $\leq$ 5.5 cm for LV end-systolic diameter, and > 27% for LV ejection fraction were identified to predict complete recovery of LV function, while QRS duration $\geq$ 120 ms was a predictor for mortality. Recently, Baruteau (34) discussed the potential significance of cardiac MRI in prognostic stratification. Elevated C-reactive protein and Fas/APO-1 were also reported to be related to decreased LV function and mortality (42). These perspectives remain to be evaluated by further studies.

Follow-up of patients with PPCM is similar with that for other forms of cardiomyopathy and LV systolic dysfunction. Considering that the recovery interval is not restricted to the first 6-12 months postpartum, it is strongly recommended to continue treatment and follow-up for a long period of time to achieve best results (37). An echocardiogram should be repeated at about every 6-12 months until recovery is

confirmed, or a plateau is reached (1). Dobutamine stress echocardiography may be performed to assess the potential for LV function recovery, by measuring the inotropic contractile reserve (46). The technique is useful especially when LV systolic function is normal, and the contractile reserve remains decreased.

One of the most important issues in PPCM is the safety of subsequent pregnancies. Even after the full recovery of LV function, the risk of relapse might be present. LV systolic function seems to be the key prognostic factor when counseling women with PPCM about the further risks. Individual planning might be done after an echocardiogram was performed:

- if LV ejection fraction is < 25% at diagnosis or incompletely recovered, the advice should be against further pregnancy (1);

- even if LV function is normal, the patients ought to have stress-echocardiography. Women with an abnormal LV inotropic response to dobutamine have a moderate risk of relapse and pregnancy is not recommended. Women with complete recovery on both echocardiography and dobutamine stress test can be informed about the low rate of complications. In this group, pregnancy can be completed in almost all cases (5).

In postpartum period, it is imperative to give contraceptive counseling and educate the patients about the existing alternatives. The combined oral contraceptives, containing estrogens and progestins are contraindicated, as estrogens increase the thromboembolic risk. Intrauterine systems are the most efficient and safe methods of contraception. Sterilization methods, including vasectomy, tubal ligation, and insertion of intratubal stents may be considered (1).

At the present time, no protocols for decision-making when counseling women with PPCM about risks of subsequent pregnancies are established. For this reason, it is advisable that every women who experienced PPCM to be considered at risk, and to be closely monitored by the medical team, in a high-risk obstetrical center.

ASPECTS OF THE MOLECULAR-GENETIC PROFILE IN PATIENTS WITH ISCHEMIC HEART DISEASE (Abstract): **Aim:** To assess the clinical and molecular-genetic aspects in patients with various forms of ischemic heart disease (IHD). **Material and Methods**: This case-control study was conducted in the interval 2007-2011 and included 405 patients with acute coronary episodes admitted to the Chisinau „Sfanta Treime" Municipal Hospital and Institute of Cardiology. Polymorphism of candidate genes angiotensin converting enzyme (ACE), angiotensin II type 1 receptors (AT1R), endothelial nitric oxide synthase (eNOS), and platelet GPIIb/IIIa receptors (PlA1/PlA2) were identified by amplified fragment length (AFLP) and restriction fragment length polymorphism (RFLP). **Results:** There were significant differences in the frequency of D risk alleles in coronary patients compared with controls (78.65% *vs.* 61.24%, p <0.05). The distribution of angiotensin II type 1 receptor A1166C gene polymorphism in the group of patients with IHD was: AA genotype - 72 (25.74%), CC genotype - 47 (16.78%), CA genotype - 161 (59.28%) patients. **Conclusions:** GPIIb/IIIa A2A2 gene haplotype is associated with susceptibility to IHD and increased prevalence of dyslipidemia, particularly in smokers. The carrier state of DD genotype and D allele of ACE gene can be used as markers of increased risk for IHD and myocardial infarction (MI) and is associated with increased blood pressure. **Key words:** ISCHEMIC HEART DISEASE, GENE POLYMORPHISM, ARTERIAL HYPERTENSION

Early multipopulational studies - ECTIM in Europe and Framingham in the USA - have demonstrated that IHD occurs as a result of the interaction between two groups of factors - genetic and environmental. Studies aimed at identifying the genes responsible for the heritability of IHD and MI have uncovered several candidate genes with different roles in vascular biology that are believed to be involved in the pathogenesis of IHD; of these more important are the genes encoding ACE, AGT1R, eNOS, and platelet GPIIIa receptors (PlA1/PlA2 polymorphism). They were investigated separately or associated in the European population, but the genetic complexity of this disease was not foreseen, new approaches being needed (1-4). Currently there is no accurate data on the clinical and evolutionary aspects in patients with ischemic heart disease in relation with the polymorphic markers of candidate genes associated with susceptibility to MI. These shortcomings determined us to study the clinical and genetic features in patients with various forms of ischemic heart disease.

MATERIAL AND METHODS

This study included 405 patients admitted in the interval 2007-2011 to the Chişinău „Sfanta Treime" Municipal Hospital and Institute of Cardiology for an acute coronary event with or without ST segment elevation. The control group consisted of 290 matched persons without IHD (data used for matching were age, gender, residence and professional activity). Sex-distribution in the study groups was uniform, male/female ratio being 2:1, that is 2 times more males ($p < 0.001$). Mean age was 57.93 ± 0.34 years, with insignificant variation in the control group ($p > 0.05$).

The study was polycentric, case-control, approved by the National Ethics Committee for Clinical Trials and Drug Development of the Ministry of Health of the Republic of Moldova (no. 331, 03.06.2010). All subjects were native-born citizens and residents in the Republic of Moldova of comparable socio-economic status and ethnically matched. Patients were included in the study in order of their hospital admission, after clinical and enzyme stabilization and obtaining informed consent, this type of patient selection ensuring randomness of the study group. Criteria for inclusion in the study were the clinical diagnosis of acute Q wave and non-Q-wave myocardial infarction, unstable or exercise angina pectoris, in agreement with the recommendations of the European Society of Cardiology (5).

Exclusion criteria: hypercholesterolemia (total cholesterol ≥ 8 mmol/ l) and secondary hypertriglyceridemia, pacemaker implant with evidence of ventricular pre-excitation, atrioventricular conduction blocks (2nd or 3rd degree sinoatrial or atrioventricular block), active liver disease, acute gastrointestinal diseases, severe kidney disease, and associated diseases that influence life expectancy.

Standard questionnaires were used to collect data on past and current medical history, examination results, and also personal and demographic data, cardiovascular risk factors, family history of coronary artery disease, hemodynamic data; lipidogram, blood glucose level, cardiac enzymes, instrumental investigations - ECG, echocardiography, coronaro-angiography.

Polymorphism of candidate genes angiotensin converting enzyme (ACE), angiotensin II type 1 receptors (AT1R), endothelial nitric oxide synthase (eNOS) and platelet GPIIb/IIIa receptors were identified by amplified fragment length polymorphism (AFLP) and restriction fragment length polymorphism, RFLP) (6-9).

Data were computer processed by variation, correlation, and descriptive analysis methods. The relationships between the studied phenomena were determined by using simple linear regression, quantitatively expressed by the correlation coefficient rxy. For estimating genetic frequencies we used POPULATION GENETIC ANALYSIS by Nei Masatoshi (1987), Molecular Evolutionary Genetics, Diploid Data Set at the Genetics Center, New York University, Langone. Frequency of studied genes loci was calculated with the help of Hardy-Weinberg equilibrium.

RESULTS AND DISCUSSION

Association of ACE insertion/deletion polymorphism (287 bp) with conventional risk factors and cardiovascular complications

Distribution of coronary patients according to ACE insertion/ deletion (I/D) polymorphism confirmed the prevalence of homozygous individuals with risk DD genotype as compared with the controls (19.64%

vs.. 11.03% ($\chi 2$ = 8.77, p <0.05), while genotype II was prevalent in the control group (33.11% *vs.*. 19.64%, $\chi 2$ 13.31, p <0.01). There were no significant differences in the number of heterozygous (ID) in both groups (60.72% *vs.* 55.86%, p> 0.05). ACE I/D polymorphism genotyping and the estimation of allele frequency revealed significant differences in the presence of risk D allele in patients with coronary heart disease compared with the controls (78.65% *vs.* 61.24%, OR = 1.29, $\chi 2$ = 8.77, p <0.05). Compared with those in which this was not present (II), the analysis of the risk factors and clinical manifestations revealed that ACE DD homozygous or ACE ID heterozygous genotypes in patients with IHD is associated with increased prevalence of hypertension (90.91% and 88.24% *vs.* 78.18%), SBP (155.32 ± 1.46 mmHg and 140.5 ± 1.31 mmHg vs.. 125.42 ± 1.36 mmHg), DBP (95.42 ± 1.35 mmHg and 90.6 ± 1.28 mmHg *vs.* 80.5 ± 1.84 mmHg) and recurrent angina (40.00% *vs.* 34.11% *vs.* 23.64%, respectively, p <0.01).

The differences between study groups reached statistical significance (p <0.05). No statistically significant differences were found between carriers of genotypes II, DD or ID in terms of degrees of hypertension. Considering the spectrum of risk factors and the clinical presentation according to ACE gene polymorphism recorded in this study, it appears that the presence of D allele and, in particular, homozygous DD state are associated with blood pressure values exceeding the optimal level (rxy = 0.81, p (DD-II) <0.01). D allele carrier state and heterozygous ID state are associated with a significantly higher risk of cardiovascular death (rxy = 0.27, p (ID-II) <0.05) and recurrence of angina symptoms (rxy = 0.42, p (ID-II) <0.05).

Association of AT1R A1166C polymorphism with conventional risk factors and cardiovascular complications

Genotype frequencies of AT1R A1166C polymorphism in the group of patients with IHD were: AA genotype was detected in 72 (25.74%) of the IHD patients, CC in 47 (16.78%) and AC in 161 (59.28%). In the control group genotype frequencies were: 31 CC carriers (10.69%), 162 AC carriers (55.86%), and 97 AA carriers (33. 40%). No significant differences in the presence of the studied genotypes were found (p> 0.05).

Genotyping of AT1R A/C polymorphism showed no conclusive differences between the presence of risk allele C in patients with coronary heart disease (72.83% *vs.* 70.71%, p> 0.05), or non-risk allele A frequency (27.17% *vs.* 29.29%, p> 0.05), compared with controls.

Comparative analysis of the characteristics of IHD patients grouped according to cytosine or adenine variants (A/C) of AT1R gene, revealed the association of homozygous CC state or heterozygous AC state with increased prevalence of hypertension (95.49% and 89.44% *vs.* 68.33%, p <0.05).

Estimation of the correlation between clinical determinants and AT1R A/C gene polymorphism showed that the presence of the risk CC genotype in the coronary patients is associated with increased prevalence of hypertension (p <0.01) compared with homozygote AA genotype (p <0.05).

Association of gene polymorphism Asp298Glu NOS with conventional risk factors and cardiovascular complications

The distribution of Asp298Glu eNOS gene polymorphism genotype frequencies in IHD patients showed no differences between IHD patients and controls in terms of frequency of AG genotype (53.21% *vs.* 57.93%, p> 0.05) and risk allele AA frequency (63% *vs.* 79%, p> 0.05). No signifi-

cant age-related differences were found, but there was a tendency towards accumulation in women (37.84% *vs.* 24.27%, p = 0.06).

Comparative analysis of characteristics of IHD patients, grouped according to Asp298Glu eNOS gene polymorphism revealed that homozygous state with risk genotype AA or heterozygous (AG) state are associated with increased prevalence of hypertension (96.00% and 87.91% *vs.* 69.64%, p <0.05), with no clear difference in terms of obesity (57.33% and 44.96% *vs.* 37.50%, p> 0.05). Analysis of clinical manifestations shows that almost 89.33% of the AA genotype carriers had hypertension grade II-III, while such levels of hypertension were found in only 69.64% of the GG carriers and 85.23% of AG carriers.

Analysis of echocardiographic findings showed reduced ejection fraction <50% in more than half of AG genotype carriers (57.05%), the same being also found in patients with genotypes GG and AA (42.86% *vs.* 46.67%, respectively) .

Estimation of the correlation between clinical determinants and eNOS gene A/G polymorphism has shown that as compared with non-carrier individuals (GG), homozygous AA state and heterozygous carriers of eNOS A/G polymorphism in coronary patients are associated with increasing prevalence of arterial hypertension (rxy = 0.84, p (AA-GG) <0.01).

Association of PlA1/PlA2 GPIIb/IIIa gene polymorphism with conventional risk factors and cardiovascular complications

Analyzing the frequencies of PlA1/PlA2 genotypes according to the polymorphism detected by Msp-I enzyme digestion we found that risk haplotype A2A2 was detected in 63 (22.50%) of the patients and 28 (09.66%) controls, the difference being statistically significant ($\chi 2$ = 16.28, p <0.001). Significant age-group differences were not found, but a trend of male prevalence (53.39% *vs.* 43.24%, p = 0.06) was noticed.

Analysis of A1A2 GPIIb/IIIa gene polymorphism genotyping revealed that mutant A2 allele tents to be more common in the IHD patients compared with controls (72.85% *vs.* 70.71%, p = 0.06). At the same time, the frequency of recessive A1 alleles in the coronary patients was lower than in the controls.

Platelet membrane glycoproteins play an important role in platelet adhesion and aggregation. The allelic variants for GPIIb/IIIa bind to fibrinogen being the key reaction in the process of platelet aggregation. The presence of P1A2 allele leads to increased functional activity of IIb/IIIa receptors and is associated with intense ADF-induced platelet aggregation *in vitro* (10).

The analysis of the relationship between the carrier-state of different genotypes and risk factors revealed a significant difference between genotypes A1A1, A1A2 and A2A2 carriers and the prevalence of smoking (53.90%, 48.68% and 69.84%, respectively, p <0.01) and mixed dyslipidemia (59.21%, 75.17% and 63.49%, respectively, p <0.05). Note the statistically significant difference between groups in terms of the share of old MI in the history of the study patients: A2A2 genotype was detected more frequently than A1A1 (20.63% *vs.* 9.21%, p <0.05).

Analysis of biochemical characteristics in relation with A1/A2 GPIIb/IIIa gene polymorphism showed that A2A2 genotype was associated with higher prothrombin levels as compared to A1A1 and A1A2 variants (106.96 ± 0.52% *vs.* 90.83 ± 0.59% *vs.* 80.00 ± 1.05%, p <0.05). Signs of grade II and III left ventricular failure (LVF) were present in 25.53% of A1A2genotype carriers, 15.87% of A2A2 genotype carriers, and 14.47% of genotype

A1A1carriers (p> 0.05).

It is noteworthy that one fourth of the risk A2A2 and A1A2 haplotype carriers presented Q wave acute MI compared with A1A1 carriers (28.36%, 22.22%, 19.73%, respectively, p <0.05).

It can be said that the presence of A_2 allele and A_2A_2 homozygous state are associated with the presence of dyslipidemia [rxy = 0.53, p(A2A2, A1A1) <0.05], smoking [rxy = 0.64, p(A2A2, A1A1) <0.01] - as risk factors, and a high frequency of previous IM.

CONCLUSIONS

Carrier state of DD genotype and D allele in ACE gene is a marker of increased risk for IHD and IM and is associated with an increased prevalence of hypertension, being positively correlated (rxy = 0.58, p <0.001) with the risk CC polymorphic variant of AT1R gene. A2A2 haplotype of GPIIb/IIIa receptor gene is associated with susceptibility to IHD and increasing prevalence of dyslipidemia, particularly in smokers. The impact of eNOS gene polymorphic markers for IHD was proved to be hypertension-mediated.

This research was funded by the Institutional Project No. 115, 06.420.036A, 2005-2010.

LARYNGEAL MORPHOLOGICAL CHANGES DUE TO GASTROESOPHAGEAL REFLUX DISEASE (GERD) (Abstract): Chronic laryngitis may have life impact on professional voice users. Besides smoking and excessive alcohol intake, GERD is a determining factor in the etiology of dysphonia. **Aim**: To evaluate the laryngeal alteration due to GERD in professional voice users. **Material and methods**: The study included 96 vocal professionals (teachers, actors, singers and priests), 58 males and 38 females, with a mean age of 38.3 ± 7.5 years, presented for chronic laryngeal symptoms. The patients filled out a standardized questionnaire and were examined laryngoscopically. **Results**: Laryngeal changes were scaled 0 (absence) to 7 (maximum) – arytenoid edema (5.07±1.08), interarytenoid edema (6.18±1.12), vocal folds edema (5.67±1.04), ventricular bands edema (4.96±0.97), laryngeal edema 4.12±0.83). **Conclusions**: Laryngoscopic changes may suggest the concomitance of GERD in professional voice users with dysphonia. **Keywords:** GERD, DYSPHONIA, VOCAL PROFESSIONALS.

Even though most otolaryngologists are aware of the pathology induced by gastroesophageal reflux disease (GERD), this relationship was more intensely studied during the last two decades (13, 14). Otolaryngologists have become extremely cautious when performing the clinical ENT examination and look for reflux signs (rashes, edema in the arytenoid mucosa and interarytenoidian area) even when they prescribe treatment for chronic laryngitis. According to the most recent surveys, laryngopharyngeal reflux (LPR) displays a complex spectrum of pathological signs (1, 2, 3, 5).

Reflux laryngitis occurs as a result of a backward flow of acid and other stomach contents into the esophagus to the larynx, resulting in a chemical burn of the lining.

The diagnosis of LPR is based on a combination of symptoms and findings in the larynx during physical examination (4, 7, 8).

The opening of the esophagus sits behind the arytenoids in the posterior part of the larynx, and that is why these areas are the most affected by reflux. The larynx shows signs of irritation and inflammation, as evidenced by the presence of redness

(erythema) and swelling (edema) of the arytenoids, interarytenoid region (the area between the arytenoids, also referred to as the posterior glottis, or, incorrectly, as the posterior commissure), and the post-cricoid region (the area behind the arytenoids that separates the larynx from the esophageal opening).

In severe cases, the reflux material can contact other parts of the larynx causing erythema and edema of the folds.

The presence of edema of the true vocal cords is highly suggestive of LPR, even in the absence of laryngeal erythema (6, 9, 10, 11).

Any activity that increases intra-abdominal pressure may exacerbate the symptoms of LPR. Such activities may include weight lifting, sit-ups, abdominal crunches, sexual intercourse, running, dancing, aerobics, public speaking, acting, and singing.

Reflux-related symptoms and clinical presentation have been identified in 4 to 10% of all the patients seen by otolaryngologists (15, 16, 17), and most likely, as these estimates are not accurate, the percentage could be even much higher. Regarding the patients with laryngeal pathology, LPR is related with these conditions or represents an etiological factor in approximately 50% of the cases (11, 13).

The most common symptoms and clinical presentations of the reflux laryngitis are:

- morning hoarseness
- the voice warms in more than 20-30 minutes
- halitosis
- throat clearing
- oral dryness
- white tongue
- *globus faringeus*
- dysphagia
- regurgitations of the gastric content
- recurrent cough
- laryngospasm,
- complication of asthma
- acute upper airways infection in children.

In addition to longer vocal warm up time, the vocal professionals and actors may also suffer other interferences in their vocal practice – frequent throat clearing, abundant expectoration, especially during the first 10-20 minutes of vocal training (16).

Some authors noticed that LPR patients do not present esophagitis-related changes, so dyspepsia and heartburn are usually absent (8, 12, 17).

The prevalence of esophagitis is relatively low, as the esophageal mucosa of the distal esophagus has its own antacid protection mechanisms which include the following:

peristalsis (quickly pushing the acid off the surface of the esophageal mucosa)

structure of the mucosa (tolerating the intermittent contact with the gastric acid)

capacity of the saliva to neutralize the acid

However, the larynx and the pharynx do not have such protective mechanisms, thus exposure to acid and pepsin may cause substantial changes at this level, whereas the esophagus may not be affected at all. According to the preliminary data reported by Axford (14), the lining of the larynx has a cell defense mechanism which is different from the esophageal mucosa and there are specific differences in the expression of the MUC genes and carbonic anhydrase in the larynx and pharynx (1, 3, 8).

If the mucosa is affected, either directly or through secondary mechanisms, changes in the laryngeal mucosa may result. Thus, it

may be directly affected by the contact with the laryngeal lining with acid and pepsin, which results in mucosal lesions. Alternatively, the irritation of the distal esophagus by the gastric acid may activate a reflex mediated by the vagus nerve, which leads to chronic cough and throat clearing, affecting the larynx lining as well (16, 17).

The bile reflux may also affect the larynx. Additionally, according to recent surveys, there are a lot of question marks concerning the pathophysiology of reflux laryngitis. Some authors consider that the decrease in salivary epidermal growth factor may be associated with reflux laryngitis (14, 15, 17).

The aim of this research study was to evaluate the laryngeal alterations due to gastroesophageal reflux disease in professional voice users

MATERIAL AND METHODS

Selection of patients groups

The cases included in the research study were selected among the patients of the "Sf. Spiridon" Emergency Hospital Iasi, ENT Department. As study material, we used a group of 96 vocal professionals (teachers, actors, singers, priests) diagnosed with chronic laryngitis between 2008 and 2010. All patients filled out a standardized questionnaire and patient meeting the clinical criteria of gastroesophageal reflux disease were included in the study. A written informed consent was obtained from all patients. The control group included 54 age-, sex- and profession- matched ENT patients with no laryngeal complaints (16,17).

Selection criteria:

- vocal professionals (teachers, actors, singers, priests)
- dysphonia for at least 3 months (chronic dysphonia)
- absence of laryngeal benign or malignant lesions
- no drug treatment that could alter the esophageal motor function or acid secretion (anticholinergics, sedatives, prostaglandins, calcium channel blockers, potassium, antibiotics, NSAIDs)
- symptomatic GERD

Exclusion criteria:

- active smokers
- chronic alcohol intake
- upper airways infections during the last month (before inclusion in the research study)
- prior history of anti-reflux surgery
- asthma

Statistical analysis

Statistical analysis was performed using *SPSS 16.0*, on Windows XP Professional platform.

RESULTS

This research survey included 58 males and 38 females, aged between 21 and 60 years, mean age 38.3 years (±7.56) and median age 39 years.

The most affected professionals considering laryngeal changes - were teachers (37.5%), followed by singers (28.12%). There was no statistically significant difference between priests and actors, considering that priests are a male-only category.

The analysis of laryngeal changes revealed the prevalence of changes in the true vocal folds, as well as in the interarytenoid area ($p<0.001$), closely followed by changes at arytenoid level, false vocal folds, and laryngeal mucosa in general (table I).

Diagnostic sensitivity of laryngoscopy for laryngeal changes was of over 50% for 8 of the 10 laryngeal signs suspected to occur following the action of the reflux.

Interarytenoid and arytenoid edema followed by vocal folds edema and erythema were the changes with the highest sensitivity (83-97%).

TABLE I

Laryngeal changes (flexible endoscopic laryngoscopy)

Laryngeal change	Research group		Control group	
	$\dot{x}$	±SD	$\dot{x}$	±SD
Arytenoid edema/ erythema	5.07	1.08	1.15	0.92
Interarytenoid edema/ erythema	6.18*	1.12	0.93	0.89
Vocal folds edema/ erythema	5.67*	1.04	0.98	0.91
Ventricular bands edema/ erythema	4.96	0.97	0.87	0.73
Laryngeal edema/ erythema	4.12	0.83	0.77	0.69

$\dot{x}$ -arithmetic mean ±SD-standard deviation *p<0.001

Specificity was highest in the patients with true vocal folds and ventricular bands erythema, followed by ventricular bands edema and laryngeal erythema (90-94%).

DISCUSSION

According to our findings, laryngeal changes were more common at the level of the vocal and interarytenoid folds (p<0.001), followed by arytenoid area and ventricular bands both before, as well as after treatment. Interarytenoid and arytenoid edemas, followed by edema and erythema of the vocal folds were found to be the changes with the highest sensitivity (83 - 97%) (16, 17).

Despite numerous studies on reflux symptoms, those mentioned above as well as many others (16, 17), there is no objective data to support the significance of the various patient complaints and changes (as a result of the performed tests) in terms of diagnosis. This issue arose as there has not been any consensus as regards “normal” among the groups of patients included in the survey. Interdisciplinary debates (most particularly, otorhinolaryngology and gastroenterology), as well as multicentric surveys are necessary to accurately determine the sensitivity and specificity of the results frequently associated with laryngopharyngeal reflux, as well as the impact of LPR on the quality of life and general health status.

CONCLUSIONS

Patients presenting with laryngeal reflux symptoms must be treated in multidisciplinary way (otolaryngologist/gastroenterologist). The positive diagnostic requires modern and accurate testing methods: flexible endoscopic laryngoscopy, pH monitoring, esophageal impedance study, upper gastro intestinal endoscopy (UGIE).

Because there is no consensus on diagnosis and treatment, this condition is frequently either over diagnosed (resulting in various invasive, useless and expensive tests, as well as the application of inefficient treatment plans), or under diagnosed (resulting in the progression of symptoms because of the lack of adequate treatment).

CORRELATION BETWEEN ASTHMA AND *TOXOCARA CANIS* INFECTION (Abstract): **The aim** of the current study was to examine the relationship between asthma and toxocariasis. **Material and methods**: We have studied 76 patients with asthma and 88 controls (without asthma) aged 5-16 years. An ELISA test based on the detection of anti-Toxocara canis (E/S antigen) serum immunoglobulin G (IgG) and E (IgE) was done in both groups. Ordinary allergens and E/S antigen of *T. canis* infections were used to evaluate cutaneous reactivity. **Results**: Seroprevalence in asthma patients was 68.42% and in the controls 13.63%. This difference was significant. The percentage of asthmatic patients with two anti-Toxocara antibodies was 26.31%, and of 4.54% in controls. All asthma patients with anti-Toxocara IgE had cutaneous reactivity to Ag E/S. **Conclusions:** Asthma patients with anti-Toxocara IgE and IgG may have toxocariasis. **Key words**: ASTHMA, HUMAN TOXOCARIASIS, CHILDREN, PARASITOSIS.

Human toxocariasis is a cosmopolite helminthic zoonosis caused by *Toxocara canis*, a dog nematode that accidentally infects man. Humans normally become infected with *Toxocara canis* S2 larvae by ingestion of eggs present in soil contamineted by dog faeces (1).

In the small intestine, at the level of duodenum or upper jejunum, eggs hatch to release S2 larvae that penetrate the small intestinal wall and begin to wander throughout the body entering in different tissues and organs: liver, lungs, brain, eyes, heart, kidney, muscle, etc., where they can survive for a long time, up to 11 years, remaining infectious and being free or encapsulated (2). S2 larvae which remain confined to the liver or other tissues and organs do not complete their life cycle in the human body, so they never reach the stage of mature adult worm (3, 4, 5).

A positive diagnosis of toxocariasis is difficult and the confirmation of this manifest or asymptomatic parasitic disease is possible by using ELISA serological test with *Toxocara canis* S2 larva secretory-excretory antigen for detecting in the blood IgG antibodies against this parasite. ELISA

immunoenzymatic reaction for the detection of circulating anti-Toxocara antibodies has high sensitivity and specificity (3).

The pathogenic action of *T.canis* in the lung parenchyma and asthma production can be explained by the effect of larval migration which results in necrosis, inflammatory reaction, and concomittantly, intratissue T. canis excretory/secretory (TES) deposits. The last reaction triggers an immunological cascade that induces inflammatory immune reactions even in the absence of larvae in the lungs. The clinical manifestations of toxocariasis, occurring after a variable period of time, are due to the fact that these larvae tend to remain dormant and continue migration, or to reinvade the tissues after a certain period of time (6, 7).

MATERIAL AND METHODS

In the study were enrolled 164 patients admitted to the clinics of Iasi „Sf. Maria" Children Hospital. The study database consisted in information obtained from patients medical records - clinical and laboratory findings and imaging data.

The patients were divided into two groups:

Group I: 76 patients diagnosed with asthma. The clinical signs were bronchoconstriction reversible spontaneously or by the administration of bronchodilator agents, wheezing, cough, dyspnea, and chest pain secondary to airway inflammation.

Group II: controls, including 88 patients infected with *T. canis* without asthma symptoms, but with symptoms of rhinitis (32 patients), dermatitis (26 patients) and rhinosinusitis (46 patients).

Asthma patients were divided into four stages: stage 1 (intermittent asthma) - 53.84%, stage 2 (mild persistent asthma) - 26.92%, stage 3 (moderate persistent asthma) - 7.69% and stage 4 (severe persistent asthma) - 11.53%.

In all patients IgG, IgE, and anti-Toxocara antibodies were determined and cutaneous hypersensitivity tests were done.

The obtained data were analyzed and expressed as percentages, and the associations between various factors were interpreted using correlation tests. *Statistica 8.0* software was used for statistical processing of the data.

RESULTS

Group I, asthma patients, had a mean age of 9.31 years, 57.9% of them were males and 42.1% females. Seroposivity rate for *T.canis* was 68.4% (52 cases), 24 female patients and 28 male patients.

Group II, controls, had a mean age of 8.12 years and a gender distribution of 27.3% females and 72.7% males. Seroposivity rate for *T.canis* was 13.6% - 12 patients, all males (tab. I).

TABLE I

Results of anti-Toxocara serology in the two groups

Serological markers for toxocariasis	Asthma	Other symptoms	p
IgE (+) IgG (-)	20 (26.31%)	4 (4.54%)	<0.01
IgE (+)	12 (15.78%)	4 (4.54%)	NS
IgG (+)	20 (26.31%)	4 (4.54%)	<0.01
IgE (-) IgG (-)	24 (31.57%)	72 (86.36%)	NS

Most asthma patients seropositive for *T.canis* had a positive IgE and IgG distribution of 26.31%.

In the control group, the distribution was uneven, two cases seropositive for *T.canis* associated with symptoms of rhi-

nosinusitis (persistent rhinitis determining a diagnosis of chronic rhinosinusitis) being identified. Of the patients with negative serology for *T.canis*, 31.6% (24 patients), were diagnosed with bronchial asthma, 75% (12 patients) had rhinitis, and 82.6% (38 patients) rhinosinusitis and all allergy tests were positive.

In asthma patients, allergen skin reactivity rate was higher than in controls: 82.6% (66 patients) and 75%, respectively. 22 patients had curataneous hypersensitivity to *T.canis* ES Ag, sex ratio 1:1.

Of the controls with positive skin reactions (tab. II), reactivity to ES Ag was found in 26 patients: 37.5% in those with a diagnosis of rhinitis, 30.4% with rinosinusitis, and 23.1% with dermatitis.

TABLE II

Results of cutaneous hypersensitivity tests in the 2 groups

	Asthma	Other symptoms	p
Toxocara canis ES *Ag*	44(57.89%)	26 (29.54%)	<0.01
Dermatophagia	42(55.26%)	40 (45.45%)	NS
Fungi	36(47.36%)	36 (40.9%)	NS
Other allergens	32(42.1%)	36 (40.9%)	NS
No reactivity	1013.15%)	22 (25%)	NS

All patients with asthma and seropositive for anti-Toxocara IgE (32 cases) showed skin reactivity to ES Ag. Similar results were seen in 4 cases belonging to the control group (tab. III). 70% (28 patients) asthma patients with positive IgG markers for T.canis showed positive skin reactivity to ES Ag.

Of the controls positive for anti-Toxocara IgG (8 patients), 6 had positive skin tests. Of the patients with asthma and negative *T. canis* serology (28 patients), 4 had positive skin reactivity to ES Ag.. Of the patients in the control group with negative serology for both immunoglobulins (76 cases), 16 reacted to *T.canis* ES Ag inoculation.

TABLE III

Results of cutaneous hypersensitivity test to ES Ag according to the positivity of serologic markers

Serologic markers for toxocariasis	Ag E/S (+)		Ag E/S (-)	
	Asthma	Other symptoms	Asthma	Other symptoms
IgE (+) IgG (-)	20	4	-	-
IgE (+)	12	4	-	-
IgG (+)	8	2	10	2
IgE (-) IgG (-)	4	26	20	60

DISCUSSION

In the group of asthma patients we noticed a positive correlation between anti-Toxocara IgE and/or IgG serological markers. In this study the determinations of anti-Toxocara IgE and/or IgG revealed a statistically significant association with asthma manifestations. This allows us to say that in asthma the clinical manifestations are more severe and aggravated on the atopic background determined by *T.canis* infection.

In the present study we found a correlation between the presence of anti-Toxocara IgE and skin reactivity both in asthma patients and controls. The results regarding IgG reactivity are not statistically significant to allow us to demonstrate a correlation between asthma, toxocariasis, and skin reactivity.

Antigenic specificity to cutaneous aller-

gens with negative serology for *T.canis* was below 20% in both study groups. The relationship between the presence of anti-Toxocara IgE, skin reactivity to ES Ag, and asthma is significant.

Migrating larvae can cause host sensitization to ES Ag with increasing IgE specificity. IgE couples to bronchial cell membrane and causes the release of an alveolar mediator that induces bronchial mucosa inflammation, and consequently bronchial asthma. A significant association between toxocariasis and high IgE levels was reported by other authors (8, 9, 10).

Asthma patients present skin reactivity to common allergens, but this reactivity is not significantly higher than in controls. On the other hand, reactivity of asthma patients to ES Ag is significantly different from that found in the control group. Although these results do not demonstrate a causal relationship, they express a significant association between cutaneous hypersensitivity to T. canis ES Ag and asthmatiform background.

CONCLUSIONS

The present study demonstrates an association between asthma and toxocariasis and suggests the need to include this parasitic disease in the differential diagnosis of asthmatiform syndrome. Determination of anti-Toxocara IgE and IgG becomes essential in the diagnosis of such patients.

Based on literature data should be consider toxocariasis when a patient, especially children older than 3 years, has asthma, hepatomegaly, hypereosinophilia, elevated IgE level, and positive epidemiology (11).

ADULT TOXOCARIASIS (Abstract): **Aim**: Epidemiological study on a statistically significant population for determining the true degree of *Toxocara canis* infections in the adults from Moldova, Romania. **Methods**: 457 patients, 416 females and 41 males (91% and 9%, respectively) entered the study. Mean age of the investigated patients was 44.50 ± 12.706 years, with small differences between sexes. 49.2% were from rural and 50.8% from urban areas. Data on living conditions, animals in the household, and source of drinking water were obtained through direct questioning. At present there is no definitive diagnostic method for Toxocara infection, as the actual sensitivity and specificity of serological tests cannot be determined accurately. IgG antibody titer specific for *T. canis* was assessed by ELISA in all study patients. **Results**: Most infections were recorded in 2009 (51.4%), 15.3% in 2008, 17.1% in 2010 14.0% in 2011, and 2.2% (10 cases) in 2012. An IgG titer of 1/100 was found in 40.7% of the patients. Toxocariasis prevalence in our geographic area was 51.7%, without significant sex differences. However, while the percentages of negative determinations were similar for both sexes (42.5% in females and 46.3% in males), almost twice more men (9.8% *vs.* 4.6% women) had a 1/10 determination, while 21,4% of the women had a 1/50 determination as compared to 9,8% of the males. The source of water was not, at least in this study group, a major cause of disease in adults. The statistical results show a major and significant influence of human contact with the dog. Thus, in dog owners 1/50 and 1/100 determinations being found in equal percentages (26% of the total), while in those having both dogs and cats the 1/100 determination was the most common (40.7% of the total). **Conclusions**: Our data can be the basis for a nation-wide seroprevalence study and programs to eradicate this infection. **Key words**: *T.CANIS,* TOXOCARIASIS, SEROPREVALENCE, IMMUNOLOGICAL DIAGNOSTIC

Toxocaroza este o zooantroponoză cu evoluție de lungă durată, recidivantă, cauzată de parazitul *Toxocara canis*, având o simptomatologie nespecifică (1). În funcție de localizarea geografică, gradul eozinofiliei, semnele sau simptomele oculare sau pulmonare, toxocaroza poate fi întâlnită sub următoarele denumiri: *ocular larva migrans* (OLM), boala Weingarten, sindromul Frimodt - Moller sau pseudoleucemia eozinofilică (2, 3).

Toxocara canis, în stadiul adult, trăieşte în intestinul subțire al câinelui iar în stadiu larvar, accidental, la om, se poate localiza

în ochi sau viscere. Infecția se produce prin ingestia de ouă embrionate de pe sol, prin consumul de fructe sau legume contaminate cu ouă, consumul de apă contaminată sau introducerea în gură a mâinilor murdare. Omul este gazdă paratenică pentru *T.canis* (4, 5, 6).

Evaluând unele studii epidemiologice la nivel mondial, seroprevalența infecției cu *T.canis* variază între 1,6% în Marche, Italia şi 92,8% în Reunion, Oceanul Indian (7-8). Studii asupra toxocarozei au fost efectuate de Crețu et al. (.9) pe 85 de donatori de sânge, din mediul urban, evidențiind o seroprevalență de 30,6 %.

MATERIAL ŞI METODE

Studiul prospectiv, efectuat în intervalul 2008 - 2011, a cuprins un lot de 457 de pacienți adulți, urmărind evidențierea incidenței cazurilor de infestare cu *T.canis* şi relația câinelui ca sursă.

Informațiile despre geofagie, mediul în care trăiesc subiecții, condițiile de trai, contactul cu animalele, prezența sau absența manifestărilor clinice subiective, au fost obținute prin interogarea directă a subiecților. Contactul pozitiv cu *T. canis* a fost apreciat prin determinarea titrului anticorpilor IgG prin metoda ELISA.

Informațiile obținute din foile de observație ale pacienților selectați au fost introduse într-un fişier, folosind programul de calcul tabelar *Microsoft Excel*, ulterior acestea fiind prelucrate statistic cu ajutorul programului *SPSS 16.0*. Compararea valorii variabilelor numerice pe subgrupuri definite de variabilele calitative s-a realizat folosind testul ANOVA.

Pacienții incluşi în studiu au provenit din județele Iaşi (58,2%) şi Vaslui (40,7%), restul județelor fiind reprezentate cu câte un caz, Bacău şi Botoşani, şi 3 cazuri Neamț. Din totalul acestora, un număr de 416 (91%) au fost femei şi 41 (9%) bărbați. Vârsta medie a lotului investigat a fost de 44,50 ± 12,706 ani, la femei de 44,35 ± 12,527 şi respectiv 45,95 ± 14,490 la bărbați (fig. 1).

Majoritatea pacienților provin din anul 2009 (51,4%); în ceilalți ani incluşi în studiu cazuistica înregistrată a fost mai slab reprezentată (15,3%, 2008; 17,1%, 2010; 14,0%, 2011), cu un minim de 10 cazuri (2,2%) în 2012.

Lotul a avut o structură uniform repartizată şi în ceea ce privește mediul de proveniență: 49,2% rural şi 5 8% urban (fig. 2).

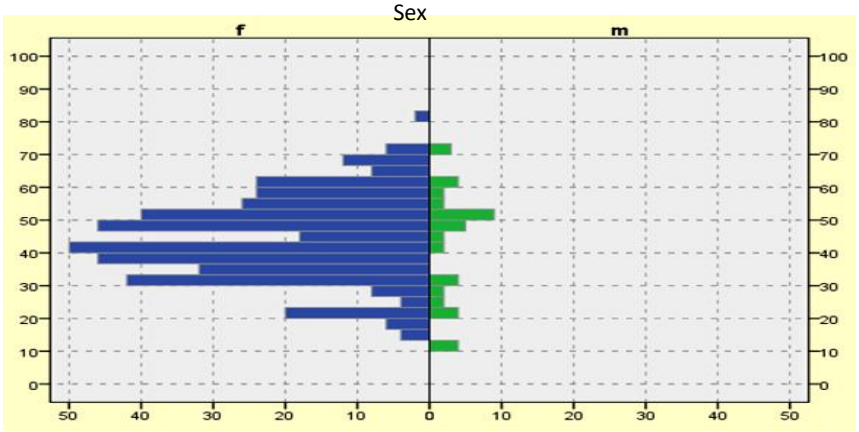

Fig. 1. Distribuția lotului pe sex şi grupuri de vârstă

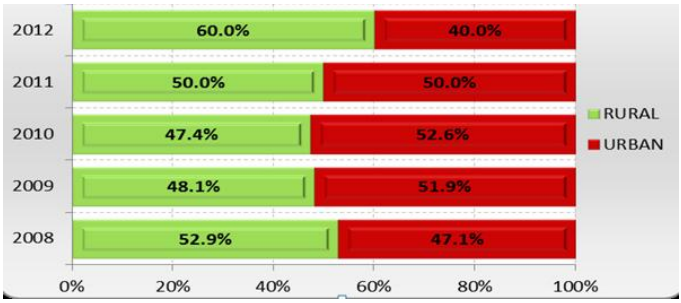

Fig. 2. Structura lotului inclus în studiu pe ani şi mediul de origine

În ceea ce priveşte sursa apei de băut, nu s-a decelat o caracteristică specifică a lotului; probabil pacienţii au consumat apă din mai multe surse, cu numai 2,2% apă de izvor. În rest, pacienţii au consumat apă de la sistemul centralizat (47,3%) şi din fântână (46,4%), iar un procentaj important au consumat apă îmbuteliată.

Pacienţii din mediul urban nu deţin animale în gospodărie în 45,1% din cazuri iar din mediul rural posedă cel puţin un câine (30.4%) sau atât câini cât şi pisici (23,6%), pentru ca să deţină numai pisici 4 (0,9%).

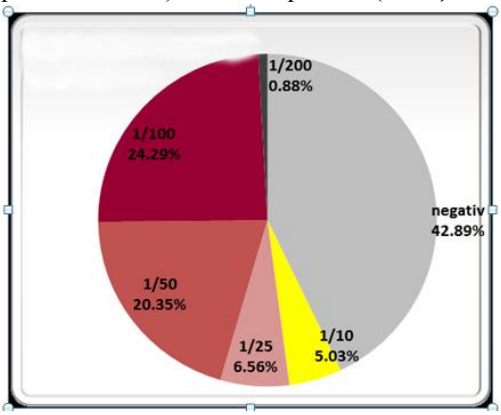

Fig. 3. Distribuţia pe titruri IgG /T.canis la lotul de paciente inclus în studiu

În ceea ce priveşte titrul anticorpilor IgG Toxocara, acesta a fost negativ în 42,9% din cazuri,1/100- 24,3% din cazuri, 1/50 - 20,4%, 1/25 -6,6%, 1/10 – 5,0% şi 1/200 -0,9% (fig. 3).

REZULTATE ŞI DISCUŢII

Studiul de faţă arată că, în lotul studiat 57,1% au avut o infecţie cu *T. canis*, 4 7 % prezentând un titru al IgG Toxocara de 1/100. Lotul a avut o distribuţie omogenă pe domicilii şi ani de studiu (fig.4).

Valorile titrului IgG Toxocara, comparative pe sex, nu a prezentat diferenţe semnificative statistic (χ^2= 6,664, p = 0,247). Se poate constata totuşi că procentajele de determinări negative sunt asemănătoare: 42,5% - femei, comparativ cu 46,3% - bărbaţi; un procentaj aproape dublu de bărbaţi (9,8%) faţă de femei (4,6%) au avut titrul de 1/1 în timp ce un procentaj dublu de femei (21,4%) a evidenţiat 1/50.

Pe medii au fost identificate,de asemenea, diferenţe semnificative statistic în ceea ce priveşte valorile titrului IgG Toxocara (χ^2 = 14,052, p = 0,015). În mediul urban prezenţa a fost 1/100 (31,6%), urmată de 1/50 (20,0%), în timp ce în rural mai frecventă este determinarea 1/50 (20,7%), urmată de 1/100 (17,2%).

Un rol major în transmiterea bolii l-a avut prezenţa câinelui în gospodărie. Se poate afirma că există o influenţă semnificativă a prezenţei animalelor în gospodărie asupra frecvenţei cazurilor cu titrul Toxocara pozitiv (χ^2 = 50,409, p = 0,000). Astfel, cel mai mare procentaj de determinări negative a fost înregistrat în rândul persoanelor care nu au animale în gospodă-

rie (55,3%), iar cel mai scăzut procentaj a fost identificat în rândul celor care dețin doar pisici (25,0%). De asemenea, tot la posesorii de pisici se observă un procentaj foarte mare de pacienți (50,0%) pentru care a fost identificată valoarea 1/5 la posesorii de câini determinările 1/50 şi 1/100 sunt în procentaje egale (26,6% din total), iar la cei care dețin atât câini cât şi pisici cea mai frecventă a fost determinarea 1/100 (40,7%).

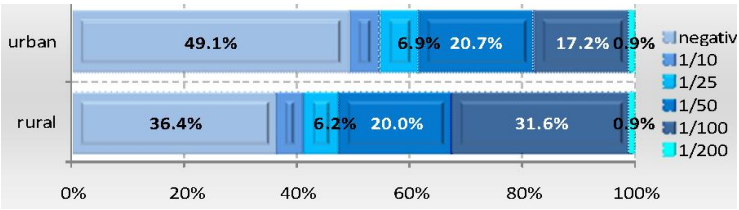

Fig. 4. Valorile comparative ale titrului IgG / *T.canis* pe mediul de origine

Datele epidemiologice, statistice şi de laborator au evidențiat ca sursă câinele. Sursa de apă potabilă nu reprezintă, cel puțin în lotul studiat, o cale de transmitere a infecției.

Seroprevalența infecției cu *T. canis* în cercetările noastre a înregistrat valori superioare celor semnalate de alți autori (7,8), dar în România nu s-au realizat cercetări pe pacienți atât din mediul urban cât şi rural şi care să nu aibă o imunodepresie secundară unei alte boli cronice, cum ar fi infecția cu HIV.

CONCLUZII

Rezultate studiului au evidențiat rolul major de sursă pentru *T. canis*, a câinelui şi transmiterea prin contact direct cu acesta.

Datele obținute pot sugera importanța unui studiu național privind seroprevalența, pentru elaborarea unor programe de eradicare a acestei zooantroponoze.

CLINICO-BIOLOGICAL ISSUES OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS (Abstract): **Aim:** to investigate clinical and biological aspects and to evaluate potential relation with activity and damage indexes in patients with Systemic Lupus Erythematosus (SLE). **Material and methods**: retrospective observational study in 30 consecutive SLE patients (ACR 1997 diagnostic criteria) assessed according to a standard protocol including demographic, clinical and biological (hematology, inflammatory, immunology) data, disease activity (SLEDAI) and damage (SLICC/ACR). **Results**: 90% SLE women with a mean age of 45.53±13.57 years and a mean age at onset of 31.10±9.20 years, presenting mainly with skin (43.33%) and small joint (56.66%) involvement, but also with renal (26.66%), cardio-vascular (26.66%) and neurological (6.66%); high anti-DNA double stranded antibodies (30% cases; mean 40.63±71.62IU/L) and low C3 levels (26.66%; mean 100.63±26.06 IU/L) have been reported, while more than 76% SLE patients displayed a low disease activity (mean SLEDAI 4±3.64) and limited damage (mean SLICC/ACR 1.4±0.85). Statistically significant correlation ($p<0.05$) have been identified between SLEDAI and SLICC/ACR ($r=0.477$), anti-DNA double stranded and SLEDAI ($r=0.515$) respectively SLICC/ACR ($r=0.404$), age at onset respectively current age and SLICC/ACR ($r_1=0.495$, $r_2=0.468$). **Conclusions:** The clinical and biological study based on data from consecutive SLE patients has offered a comprehensive approach of different disease subtypes in North-East Romania. The predominance of currently low disease activity and minimal damage disease profile could reflect either SLE particularities or the expected effects of early individualized therapy. **Key words**: SYSTEMIC LUPUS ERYTHEMATOSUS, CLINICAL MANIFESTATIONS, DISEASE ACTIVITY, DISEASE DAMAGE.

Lupusul eritematos sistemic (LES) este o condiție inflamatorie cronică, prototipul bolilor autoimune, numeroşi factori de ordin genetic, imunologic, hormonali şi de mediu fiind implicați în patogenia complexă a acestei afecțiuni. Cu o prevalență majoritară la sexul feminin în decadele treicinci de vârstă, boala prezintă un tablou clinic polimorf, cu afectare multisistemică ce se remarcă prin frecvența crescută a

manifestărilor cutaneo-mucoase, musculo-scheletale, renale, cardio-vasculare, pulmonare, neuro-psihice şi gastro-intestinale (2, 3). Bulversarea imună caracteristică bolii reține atenția printr-o paletă largă de auto-anticorpi, de la cei cu specificitate ridicată pentru lupus (anticorpi anti-ADN dublu catenar, anticorpi anti-Sm), la cei raportați şi în alte patologii reumatismale cu determinism imun (anticorpi antinucleari totali, anti-Ro/SS-A şi anti-La/SS-B, anticorpi anti-fosfolipidici), cu rol esențial în guvernarea proceselor patologice definitorii pentru LES (1). Mai mult, recentele progrese în înțelegerea imunopatogeniei afecțiunii au permis introducerea de noi instrumente de apreciere a activității şi distrucției tisulare, precum şi identificarea de noi ținte terapeutice.

Studiul de față şi-a propus analiza aspectelor clinice şi paraclinice precum şi analiza spectrului de relații dintre tabloul clinic, activitatea bolii şi indicele lezării organice la pacienți cu LES.

MATERIAL ŞI METODE

Am realizat un studiu observațional retrospectiv pe un lot de 30 pacienți consecutivi diagnosticați cu LES (criteriile *American College of Rheumatology* -ACR 1997) aparținând județelor din regiunea de Nord-est a țării, spitalizați în Clinica Reumatologie, Spitalul Clinic de Recuperare Iaşi în intervalul ianuarie-martie 2011.

Pacienții au fost evaluați conform unui protocol standard ce a inclus date demografice (sex, vârsta la debutul bolii şi la examinare), parametri clinici şi paraclinici (hematologici, inflamatori, imunologici), indicele de activitate al bolii (*Systemic Lupus Erythematosus Disease Activity Index,* SLEDAI), gradul de distrucție tisulară (*Systemic Lupus International Collaborating Clinics/American College of Rheumatology,* SLICC/ACR), precum şi particularitățile terapeutice. SLEDAI reprezintă un indice compozit de evaluare a activității bolii raportat la ultimele 10 zile, ce cuprinde 24 de variabile clinice şi de laborator, cu valori cuprinse între 0 şi 105, scorurile înalte definind activitatea înaltă a bolii. SLICC/ACR este un indice global de evaluare a gradului de distrucție tisulară la nivelul a 12 sisteme/organe, evidențiind modificări ireversibile cu impact pe termen lung asupra mortalității în lupus.

Studiul s-a desfăşurat conform normelor etice în vigoare. Studiul statistic (descriptiv, analitic) s-a realizat cu ajutorul programului *SPSS 19.0.*

REZULTATE ŞI DISCUȚII

*Date demografice***.** Lotul studiat a fost alcătuit majoritar din femei (90%) aparținând mediului urban (75%), cu o vârstă medie de 45,53±13,57 ani şi vârsta medie de debut a bolii de 31.10±9.20 ani, profil ce corespunde datelor raportate in literatură (1, 2, 3). Repartiția pe grupe de vârstă a demonstrat procente comparabile pentru decadele cinci şi şase (22% respectiv 25%), în timp ce unul din cinci pacienți cu lupus s-a încadrat în categoria de vârstă sub 40 ani (20%).

*Tablou clinic***.** Frecvența diferitor manifestări clinice specifice lupusului raportat la criteriile de diagnostic ACR 1997, incluzând patologia musculo-scheletală, cutanată, cardio-vasculară, renală şi neurologică, precum şi repartiția acestora pe grupuri (tab. I).

Manifestările cutanate (fotosensibilitate, *rash* malar "în fluture") şi cele musculo-scheletale (poliartrita non-erozivă afectând articulațiile mici ale mâinilor, bilateral şi simetric) au fost cel mai frecvent raportate

în lotul studiat, reprezentând 43.33% şi respectiv 56,66%, fiind prezente încă din etapa de debut a afecţiunii şi înregistrând severitate medie la momentul studiului; nici un pacient nu a prezentat afectare severă de tipul serozitei, manifestărilor psihiatrice sau renale active la evaluarea actuală. Mai mult, nu s-a raportat implicarea sistemelor gastro-intestinal, ocular şi nu au fost depistate adenopatii. Pentru definirea afectării cardio-vasculare au fost urmărite modificările ECG (aritmii, fenomene ischemice) şi trombozele venoase profunde, fenomene depistate în 26.66% cazuri. Aproximativ un sfert din pacienţii studiaţi au asociat comorbidităţi în sfera cardio-vasculară de tipul hipertensiunii arteriale (23%) şi în sfera metabolică, de tipul dislipidemiei (20%).

Tablou paraclinic. Principalele modificări paraclinice reflectă perturbări hematologice şi de natură inflamatorie şi imunologică (tab. II).

*Anomalii hematologice***.** Reţinem prezenţa izolată a citopeniei pe toate liniile hematologice, cu distribuţie variabilă pe serii celulare, procentul de pacienţi cu anemie (26,66%) fiind superior celui cu trombocitopenie (10%) şi respectiv leucopenie (10%), în timp ce bicitopenia s-a înregistrat la 16,66% pacienţi. Peste jumătate din cazuri nu au prezentat implicare hematologică la momentul iniţierii studiului.

TABELUL I

Frecvenţa manifestărilor clinice şi distribuţia pe grupuri de vârstă în lotul studiat

Manifestări evaluate	**N=30**	**%**
Cutanat (fotosensibilitate, rash malar)	13	43,3
Artrită (poliartritănon-erozivă simetrică)	17	56,66
Cardio-vascular	8	26,66
Afectare renală (nefropatie**)**	8	26,66
Afectare neurologică	2	6,66
Afectare gastro-intestinală	0	0
Serozite (pleurezie, pericardită)	0	0

	<40 ani (N=8)	**41-50 ani (N=9)**	**51-60 ani (N=10)**	**>60 ani (N=3)**
Cutanat	2	4	6	1
Articular	3	9	4	1
Cardio-vascular	0	1	5	2
Renal	3	1	4	0
Neurologic	0	1	1	0

*Sindromul imunologic***.** Deşi LES este prin excelenţă caracterizat de un profil complex de autoanticorpi, studiul actual a luat în atenţie doar bilanţul imunologic clasic ce presupune determinarea anticorpilor cu relevanţă pentru diagnostic, propuşi în cadrul criteriilor de diagnostic, şi anume: anticorpii anti-ADN dublu catenar (anti-ADNdc), anti-Sm, anticorpii anti-nucleari totali, precum şi anticorpii anti-fosfolipidici. Se remarcă pozitivitatea titrului anticorpilor anti-ADNdc în doar 30% din ca-

zuri (valoare medie 40,63±71,62UI/l, metoda imunoenzimatică cu detecție prin fluorescență) și a anticorpilor anti-fosfolipidici în 17% cazuri. Dat fiind importanța cuantificării nivelului complementului seric și mai ales a fracțiunilor C3 și C4 în relație cu activitatea LES, am luat în atenție în studiul efectuat și acești parametri, identificând valori scăzute ale C3 în 30% din cazuri, cu o valoare medie de 100,63±26,06 UI/l.

TABELUL II

Frecvența anomaliilor paraclinice în lotul studiat

Modificari hematologice	**Nr. cazuri**	**% ***
Anemie	8	26,66
Leucopenie	3	10
Trombocitopenie	3	10
Bicitopenie	5	16,66
Modificări inflamatorii		
CRP crescut	4	13,33
VSH crescut	10	33,33
Modificări imunologice		
C3 scăzut	9	30
Anticorpi anti-ADN dublu catenar crescut	9	30

***Pentru valorile mai mici de 10, procentele sunt orientative.

Formele active de boală se caracterizează prin valori crescute ale anticorpilor ADNdc și valori scăzute ale complementului, atestând consumul (complexe imune circulante, depozite tisulare de complexe imune fixatoare de complement), dinamica acestor parametri imunologici putând cuantifica răspunsul la tratament și anunța posibilitatea instalării unui nou episod de activitate (3,4). Analiza relației între titrul anticorpilor anti-ADNdc și concentrația serică a C3 a relevat o corelație indirectă, de intensitate medie, semnificativă statistic (Pearson, r=0,36 p= 0,047), confirmând datele din literatură (11): formele de boală cu un titru înalt al anticorpilor anti-ADNdc se caracterizează printr-un nivel scăzut al complementului seric.

Sindromul inflamator. Sindromul inflamator reține atenția doar într-o treime din cazurile studiate (33,33%), dominantă fiind creșterea VSH (valoare medie 24,73±19,84 mm/oră); menționăm un titru anormal al proteinei C reactive serice (valoare medie 1,05±0,9 mg/dl) detectat în doar 13,33% din cazuri. Lupusul este caracterizat de ascensionarea VSH și valori ale CRP în interval de normalitate (12), creșterea acesteia, și în mod particular a *high sensitivity* CRP (hsCRP) fiind importantă pentru evaluarea statusului infecțios intercurent la astfel de pacienți (13). Măsurarea CRP și a hsCRP în LES este utilă în diferențierea între infecție și etapele de recădere (12), nivelul hsCRP fiind mult mai mic în puseele de activitate (13); mai mult, hsCRP poate fi considerat factor de predicție al infecțiilor active în LES (13). Cu toate că literatura de specialitate citează o corelație de intensitate ușoară, în studiul de față s-a pus în evidență o corelație semnificativă statistic, medie, directă,între valorile celor doi markeri de inflamație (Pearson, r= 0,55

p=0,01), fapt explicat de posibile infecţii subclinice neevaluate în protocolul de studiu.

Indicele de activitate SLEDAI. Cuantificarea indicelui de activitate al lupusului conform SLEDAI a indicat prevalenţa majoritară a cazurilor de boală cu activitate uşoară (76.66%), valorile medii ale SLEDAI fiind 4±3,64. La polul opus se situează formele de boală cu activitate foarte înaltă (3,33%) şi cele inactive, aflate in remisiune (6,66%) (tab. III).

TABELUL III

Indicii de activitate (SLEDAI) şi distrucţie (SLICC/ACR) şi repartiţia pe grupuri de vârstă în lotul studiat

Grupuri vârstă (ani)	Subgrupe SLEDAI- număr de pacienţi				
	0 Fără activitate	**1-5 Activitate uşoară**	**6-10 Activitate moderată**	**11-19 Activitate înaltă**	**>20 Activitate foarte înaltă**
<40	1	7	0	0	0
41-50	1	6	2	0	0
51-60	0	8	1	0	1
>60	0	2	0	1	0

Grupuri vârstă (ani)	SLICC/ACR			
	0	**1**	**2**	**3**
<40	3	3	2	0
41-50	0	7	2	0
51-60	1	2	5	2
>60	0	1	1	1

Indicele de distrucţie organică tisulară SLICC/ACR. Distrucţia tisulară caracteristică LES are în atenţie trei componente esenţiale şi anume: procesul imunologic ce defineşte boala, potenţialul advers al medicaţiei folosite, precum şi intervenţia comorbidităţilor, datele fiind cel mai bine reflectate de indicele SLICC/ACR. Studiul efectuat a relevat valori medii ale SLICC/ACR de 1,4±0,85, variind în intervalul de 0 şi 3 puncte. Patru dintre cazurile evaluate nu au prezentat leziuni distructive permanente, în timp ce marea majoritate (76,66%) au cumulat punctaje de 1 şi 2.

Studiul potenţialelor relaţii între activitatea respectiv distrucţia tisulară din lupus, pe de o parte, şi aspectele demografice, clinice şi paraclinice, pe de altă parte, a permis caracterizarea extensivă a lotului de pacienţi. Dacă parametrii demografici respectiv vârsta şi vârsta la debutul afecţiunii nu sunt relevanţi pentru nivelul de activitate al LES (p>0,05), indicele de distrucţie tisulară se corelează direct cu ambii parametri (Pearson:r=0,495, p=0,005 respectiv r=0,468, p=0,004).

Principalul aspect clinic cu relevanţă pentru indicele SLEDAI a fost afectarea cutanată (Pearson, r=0,381, p=0,038), în timp ce componenta musculo-scheletală, statusul cardio-vascular şi manifestările renale nu au fost majoritar implicate în determinismul activităţii bolii (p>0,05). Mai mult, nu a fost demonstrată semnifica-

ție statistică nici pentru relația indice SLICC/ACR - elemente clinice (cutanate, musculo-scheletale, renale, cardio-vasculare) (p>0,05).

Anomaliile hematologice, izolate sau afectând mai multe linii celulare, nu s-au reflectat semnificativ în indicii de activitate şi de distrucție tisulară analizați (p>0.05). Deşi parametrii inflamatori (VSH, CRP) şi fracțiunea C3 nu au prezentat asociere cu SLEDAI respectiv SLICC/ACR (p>0,05), nivelul seric al anticorpilor anti-ADNdc a fost considerat apanajul formelor active de boala (Pearson, r=0,515, p=0,004), dar şi un element determinant pentru fenomenele distructive (Pearson, r=0,404, p=0,002), relația fiind directă, de intensitate medie.

Dacă pentru relația anticorpi anti-ADNdc – indice de activitate SLEDAI studiul realizat se înscrie în ceea ce raportează literatura de specialitate (14), pentru ceilalți parametri imunologici (în mod particular C3) şi inflamatori (VSH, CRP) datele obținute raportate la activitatea şi distrucția din LES au fost discordante față de literatură. Astfel, o serie de cercetări recente (14) demonstrează faptul că formele de boală cu activitate înaltă definite prin scoruri crescute ale indicilor de activitate ai lupusului, în particular pentru scorurile SLEDAI-2k (*Systemic Lupus Erythematsus Disease Activity Index 2000*) şi BILAG (*British Isles Lupus Assessment Group)* se asociază cu creşterea VSH, scăderea concentrației C3 şi C4, creşterea nivelului anticorpilor anti-ADNdc (p<0,01). În plus, toți aceşti parametri imunologici şi inflamatori sunt importanți pentru evaluarea şi monitorizarea răspunsului terapeutic la pacienți cu LES (14).

Relația semnificativă directă, de intensitate medie între activitatea şi potențialul distructiv tisular al LES (Pearson, r=0,477, p=0,008), validează faptul că unul din cele trei elemente generatoare de distrucție este procesul lupic *per se*, alături de efectele adverse ale medicației şi comorbiditățile sau complicațiile bolii.

*Terapie***.** Standardul terapeutic actual al LES este reprezentat de corticosteroizi, medicație remisivă (azatioprină, ciclofosfamidă, micofenolat mofetil, antimalarice de sinteză) şi mai nou introdusa în practica zilnică medicație biologică (belimumab), alegerea schemei terapeutice optime fiind guvernată de forma şi activitatea bolii. Majoritatea pacienților monitorizați în studiul de față a primit doze joase de corticoterapie cronică (5-20 mg/zi prednison sau echivalent), antimalaric de sinteză (200 sau 400 mg/zi) şi azatioprină (50-150 mg/zi, echivalentul a 2 mg/kg corp/zi), pacienții cu afectare renală având în protocolul terapeutic un al doilea imunosupresor, respectiv ciclofosfamida (800-1000 mg/administrare, *pulse*-terapie lunară).

Tripla asociere corticoterapie-azatioprină-hidroxicloroquin a fost raportată la 40% dintre pacienți, în timp ce monoterapia cu antimalaric de sinteză a fost indicată în 16,66% din cazuri. Nici unul dintre pacienții evaluați nu a primit micofenolat mofetil sau terapie biologică.

CONCLUZII

Studiul aspectelor clinico-biologice şi terapeutice la pacienții consecutivi cu LES internați într-o clinică de specialitate a permis o cunoaştere mai aprofundată a profilului cazurilor de lupus existente în populația din regiunea de nord-est a țării. Mai mult, cuantificarea activității şi distrucției tisulare prin indici validați, SLEDAI şi SLICC/ACR, precum şi analiza spectrului de relații între manifestările clinice, bulversarea biologică şi activitatea

sau distrucția caracteristice bolii a relevat impactul diferitelor opțiuni terapeutice disponibile asupra fenomenelor patogenice caracteristice afecțiunii.

Datele obținute confirmă aspectele demografice, clinice şi biologice consacrate şi anume: frecvența crescută la sexul feminin, cu debut în etapa de vârstă fertilă, polimorfismul clinic, rolul anomaliilor imune în evaluarea activității bolii; predominanța formelor de boală cu indici de activitate şi distrucție cu valori minim modificate este interpretată fie în contextul unor subtipuri de LES cu severitate joasă si evoluție benignă, fie în contextul unei terapii patogenice corect, precoce administrate şi strict monitorizate, cu impact asupra profilului de severitate şi evolutiv al bolii.

QUALITY OF LIFE AND FECAL CALPROTECTIN IN INFLAMMATORY BOWEL DISEASES (Abstract) Inflammatory diseases (IBD) are chronic disorders marked by periods of activity that require repeated in-hospital care, expensive surgical treatment with multiple side effects which affect the quality of life in these patients. Mucosal healing is associated with sustainable remission and a low risk of surgical intervention in these patients. **Aim**: To evaluate the correlations between fecal calprotectin (used as a marker of endoscopic inflammation) and quality of life (assessed by means of the IBDQ-32 questionnaire). **Material and methods:** A prospective study that includes 60 patients with IBD. Fecal calprotectin and Inflammatory bowel disease questionnaire-32 were performed in all patient. **Results:** The average value of fecal calprotectin was 247.38±345.77µg/g. The average total IBDQ was 137.42±38. There are negative statistical correlations between the activity of the disease assessed by means of the UCDAI and CDAI scores in the two studied disorders and the quality of life assessed by means of the IBDQ-32 score. We noticed significant correlations between the values of fecal calprotectin and the quality of life. **Conclusions:** The activity of the disease had a negative impact on the quality of life in the patients with IBD. Clinical manifestations are more likely to affect quality of life compared to the endoscopic activity of the disease. **Keywords:** INFLAMMATORY BOWEL DISEASE, QUALITY OF LIFE, FECAL CALPROTECTIN.

Inflammatory bowel diseases (IBD) are chronic disorders marked by periods of activity that require repeated in-hospital care, expensive surgical treatment with multiple side effects which affect the quality of life in these patients. It has been reported (1) the fact that mucosal healing is associated with sustainable remission and a low risk of surgical intervention in these patients. Until recently, colonoscopy assessment was essential in identifying the endoscopic activity in these patients.

Numerous studies (2, 3, 4) have demonstrated strong statistical correlations between the value of fecal calprotectin and the activity of the disease, this being also used as predictor of remission. Presently, fecal calprotectin is also accepted in the international diagnosis and treatment guides for IBD (5, 6).

Health is a very important component of quality of life, defined from several perspectives (7). Quality of life assessment tools have been increasingly used over the last period. These tools complement clinical and biological assessments of various disorders, in assessing medical services, the patient's perspective on the disorders they suffer from and the necessary treatments, the need - as perceived by the patient - regarding their healthcare, the patient's preference for a specific treatment, as well as the patient's expectations regarding the therapeutic results (8, 9). IBDQ-32 (Inflammatory Bowel Disease Questionnaire) is one of the most widely used questionnaires in assessing quality of life (QoL).

Starting from these prerequisites, we conducted a study assessing the correlations between fecal calprotectin (used as a marker of endoscopic inflammation) and quality of life (assessed by means of the IBDQ-32 questionnaire).

MATERIAL AND METHODS

We conducted a prospective study that included 60 patients with mean age 45±14.7 years, from whom 38.3% were women diagnosed with IBD. All subjects were performed a complete clinical-biological prophylaxis one day prior to the fecal sample collection for calprotectin measurement. The study included patients with a clinical, biological, endoscopic and histological diagnosis of IBD. The patients who had previously taken non-steroidal anti-inflammatory drugs, those with non-specific colitis, or with superinfections or colon neoplasm were excluded from the study.

In ulcerative colitis (UC), the activity was assessed based on the Ulcerative Colitis Disease Activity Score (UCDAI); this consists of three elements: frequency of the stools, rectal bleeding, the physician's global assessment and endoscopic activity. Remission was defied as a Mayo score ≤ 2. In Crohn's disease (CD), the disease activity was assessed based on the Crohn's Disease activity index (CDAI). Clinical remission was defined as a CDAI score <150. Fecal calprotectin was measured through the ELISA method. The samples were collected a day before the colonoscopy. Remission was considered for a fecal calprotectin value of < 30 µg/g.

Nineteen patients were diagnosed with CD (31.66%) and 41 with UC (68.33%). Thirty patients (50%) showed disease activity (58.53% UC and 31.57% CD) (fig. 1).

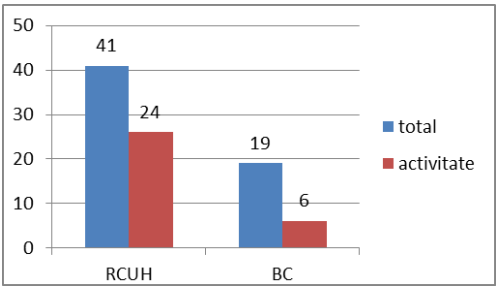

Fig. 1. Patients distribution based on disorder and activity

RESULTS

Based on lesion location, 68.21% of the patients with UC patients had pan-colitis and 29.26% had left colitis. About the patients with CD, 47.36% of patients had lesions located at colon level, 36.84% had ileo-colonic lesions and only 15.78% patients had lesions located at intestine level (fig. 2).

The average value of fecal calprotectin was 247.38±345.77 µg/g. The average total IBDQ was 137.42±38.

Analyzing the data obtained for the patients included in the study, we notice that there are negative statistical correlations between

the activity of the disease assessed by means of the UCDAI and CDAI scores in the two studied disorders and the quality of life assessed by means of the IBDQ-32 score (fig. 3).

We noticed significant correlations between the values of fecal calprotectin and the quality of life generally (fig. 4) and, in particularly in UC (fig. 5) as well as in CD (fig. 6).

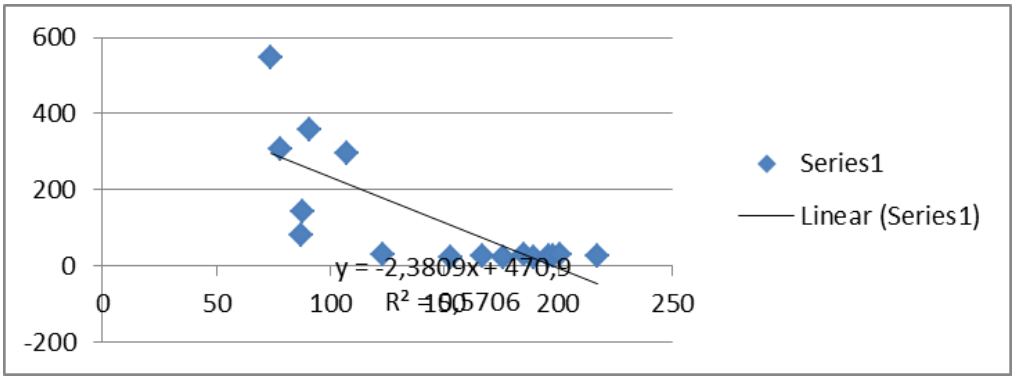

Fig. 6. Correlations between quality of life assessed by means of IBDQ-32 and the endoscopic activity of Crohn's disease assessed by means of fecal calprotectin

DISCUSSION

The concept of quality of life can only be discussed in correlation with health. If in the past, death causes and morbidities represented the main indicators of heath, presently, due to the increase in life expectancy, assessments are increasingly focused on the relationship between health and quality of life (10).

Despite its chronic evolution throughout life, IBD does not affect mortality, while it can influence he patient's morbidity and quality of life (11).

The early onset, the activity periods, the associated pathologies and their treatment are likely to impact the patients not only physically, but also by limiting their social and emotional life, their educational and professional activities. These diseases can lead in time to the impairment of their quality of life. In the studied samples, the total IBDQ-32 score varied between 67 and 207, with an average value of 137.42. To date, there is little data on establishing of a threshold of the total IBDQ-32 score. There is no defined interval within which the QoL of patients with IBD assessed by means of this instrument could be considered normal.

Compared to the study of Rubin *et al.* (12), in which the average value of the total IBDQ score was 94.1, the average value of the total IBDQ-32 score in the present study was significantly higher. Compared to other recent studies using the same tools for QoL assessment, and which reported average values of the total IBDQ-32 score of 186, respectively 159.5 (13, 14) the average value of the total IBDQ-32 score obtained in our study was lower.

Fecal calprotectin is an enterodimer present in the cytoplasm of the neutrophils. It is composed of two calcium-binding proteins. (S100A8 and S100A9) and it constitutes approximately 60% of the cytosoluble proteins of the neutrophils. Under these circumstances, calprotectin is a marker of neutrophil influx in the colon and thus, indirectly, a marker of intestinal inflammation (15).

Fecal calprotectin has been heavily studied over the last years, as a surrogate marker in inflammatory diseases about the differentiate diagnosis, the evolution of the disease, or treatment monitoring. The election method used in most of the studies was ELISA, and the cut-off values established by tests were considerably varied (16).

In our study, we used the cut-off value 30 μg/g, as the limit for predicting the endoscopic activity.

The data analyzed on the studied sample of patients confirms previous studies conducted in the clinic (17, 18). We notice a negative correlation between the quality of life and the disease activity, which translates in a more influenced quality of life in the patients with more severe forms of the disease.

About the use of calprotectin as a marker of endoscopic activity, the analyzed data demonstrated a negative correlation between it and the quality of life assessed by means of the IBDQ-32 questionnaire, lower than in the assessments performed by means of disease activity questionnaires, which shows that the endoscopic activity of the disease contributes less to the quality of life, while the clinical symptoms have a higher weight. Analyzing the two disorders separately, we notice a better correlation of quality of life with endoscopic manifestations in patients with CD compared to patients with UC. Nevertheless, the difference is not significant and, even more so, the sample of patients with CD was much smaller, and most patients were in remission.

Starting from this data, we can hope that improving quality of life and through specialized psychological intervention, we will succeed in reducing the number and severity of outbreaks. On the other hand, an efficient management of the disease can lead to significantly improved quality of life in these patients.

CONCLUSIONS

In our study, the activity of the disease had a negative impact on the quality of life in the patients with IBD. We found significant negative correlations between the activity of the disease evaluated by clinic-biological scores and the quality of life both in UC and in CD. Also, the endoscopic activity evaluated by fecal calprotectin correlates with the quality of life. Although, clinical manifestations are more likely to affect quality of life compared to the endoscopic activity of the disease.

CORRELATION BETWEEN COGNITIVE IMPAIRMENT AND CARDIOVASCULAR RISK FACTORS IN DIALYSIS VS. NON-DIALYSIS ELDERLY PATIENTS (Abstract): The emergence or worsening of cognitive impairment is a consequence of the aging process. Geriatric depression occurs due to cognitive impairment associated with aging, and as it develops, it also affects the cognitive function. **Aim:** To analyze retrospectively over a period of 6 months the clinical parameters and biological differences of the depression and cognitive impairment in dialyzed and non-dialyzed elderly patients. **Material and methods**: There were 63 patients over 65 years included in the study (29 patients admitted to the Geriatric Department of the "C. I. Parhon" Hospital, Iaşi, and 34 patients that were in the renal dialysis program into the Transplant Centre Iaşi) that were evaluated in terms of cognitive status and level of depression through the following tests: MMSE (the cognitive impairment severity assessment), the Geriatric Depression Score, the modified Hachinski Ischemic Score (for vascular dementia). The resulting data were interpreted statistically by SPSS 12.0 software and the results were evaluated by t- Student test ($p < 0.05$). **Results**: The average age was 73.2 + / -6.1 for non-dialyzed patients group and 69.8 + / - 4.6 for dialyzed group. Body mass index (BMI), hemoglobin, glucose and lipids were similar for both categories of patients. In the dialyzed group, depression is correlated with an elevated blood triglycerides, and the vascular dementia is correlated with glucose levels ($p=0.04$). Cognitive impairment is more accentuated in the dialyzed group compared to the non dialyzed one. **Conclusions**: Elderly dialyzed people are likely to develop more frequently and more severely vascular dementia than non-dialyzed old people, probably in the context of the factors that are related with dialysis itself. **Key words**: CARDIOVASCULAR RISK FACTORS, COGNITIVE IMPAIRMENT, CHRONIC RENAL DISEASE, ELDERLY.

Înaintarea în vârstă se caracterizează prin apariția sau agravarea tulburărilor cognitive. Deficitul cognitiv uşor a devenit cel mai frecvent termen utilizat, fiind definit ca un declin silențios al funcțiilor cognitive cu conservarea activităților fizice zilnice. Acest tip de deficit cognitiv uşor se poate situa între starea cognitivă normală şi demență, majoritatea tipurilor de demență fiind precedate de o stare prodromală de deteriorare cognitivă uşoară (1).

Factorii de risc pentru tulburările cogni-

tive includ: sexul masculin şi prezenţa în antecedente a hipertensiunii arteriale, infarctul miocardic, ateroscleroza, diabetul zaharat, sindromul dislipidemic, accidentul vascular cerebral constituit sau tranzitor.

Depresia geriatrică apare pe fondul disfuncţiilor cognitive asociate înaintării în vârstă şi, pe măsură ce se dezvoltă, afectează ea însăşi funcţionalitatea cognitivă (2).

Studiul nostru îşi propune evaluarea relaţiei dintre gradul de afectare cognitivă la pacientul vârstnic cu boală cronică de rinichi aflat sau nu în program de supleere renală.

MATERIAL ŞI METODE

Studiul a fost realizat pe o perioadă retrospectivă de 6 luni, incluzând un lot de 63 de pacienţi cu vârsta peste 65 ani şi cu boală cronică de rinichi în diferite stadii, din care: 29 internaţi în Clinica de Geriatrie a Spitalului Clinic Dr."C.I.Parhon", Iaşi şi 34 în program de supleere renală în cadrul Centrului de Dializă şi Transplant Iaşi.

Au fost evaluaţi din punct de vedere al severităţii disfuncţiei cognitive prin testele: MMSE (Mini Mental Stage Evaluation), Scorul de Depresie în Geriatrie, Scorul Ischemic Hachinski modificat (pentru demenţa vasculară) (tab. I).

Evaluarea severităţii disfuncţiei cognitive se defineşte astfel: forma uşoară = MMSE > 21, moderată = MMSE 10 – 20 şi severă = MMSE < 10.

TABELUL I

Structura testului pentru lotul de pacienţi incluşi în studiu

I	*Orientare*	*Punctaj*
1	În ce an, anotimp, zi a săptămânii, zi din lună, lună, suntem	5
2	Unde ne aflăm: ţară, judet, oraş, spital, etaj	5
II	*Înregistrarea informaţiilor*	
1	Rostiti numele a 3 obiecte obişnuite (măr, masă, monedă). Între fiecare cuvânt faceţi câte o pauză de 1 secundă. Cereţi pacientului să le repete pe toate 3. Un punct pentru fiecare cuvânt corect. Repetaţi până le memorează	3
III	*Atenţie şi calcul*	
1	Numărare inversă: de la 100 scăzând 7, opriţi după 5 răspunsuri corecte Test alternativ: rostirea cuvântului AVION invers	5
IV	*Reproducerea informaţiilor*	
1	Întrebaţi cele 3 cuvinte memorate anterior	3
V	*Limbaj*	
1	Denumirea unui creion şi a unui ceas	2
2	Repetarea propoziţiei: capra neagră calcă piatra	1
3	Înţelegerea unei comenzi: luaţi o foaie de hârtie, împăturiţi-o şi aşezaţi-o pe podea	3
4	Citirea şi executarea comenzii: închideţi ochii	1
5	Scrierea unei propoziţii	1
6	Copierea unui desen	1
	Scor total	30

Factorii de risc cardiovascular analizaţi au fost: obezitatea (IMC), anemia (hemoglobina), diabetul zaharat (glicemie), sindromul dislipidemic (colesterol, trigliceride).

Datele obținute au fost interpretate statistic prin programul *SPSS 12.0* iar rezultatele au fost evaluate prin testul t-Student ($p<0,05$).

REZULTATE

Evaluări clinice şi de laborator. Vârsta medie la pacienții nedializați a fost de 73,2 ± 6,1 ani, respectiv 69,8 ± 4,6 la cei dializați (fig. 1).

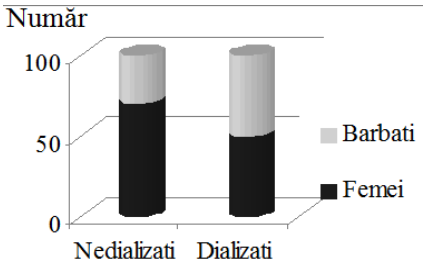

Fig. 1. Vârsta medie la cele două loturi

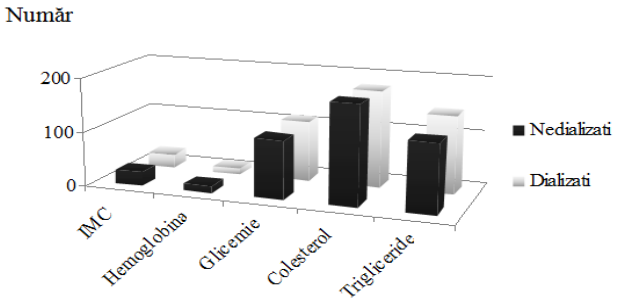

Fig. 2. Valorile parametrilor biologici comparativ la cele două loturi de pacienți incluşi în studiu

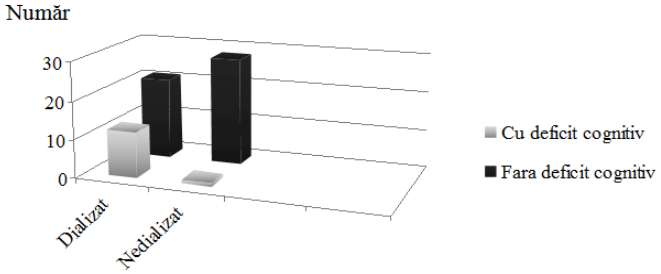

Fig. 3. Nivelurile comparative ale deficitului cognitiv la lotul dializat şi cel nedializat

La cele două loturi de pacienți, IMC-ul, valorile hemoglobinei, glicemiei şi ale lipidelor nu au prezentat diferențe semnificative (fig. 2).

În cadrul lotului dializat s-a constatat că afectarea cognitivă are niveluri de intensitate semnificativ mai ridicate, comparativ cu pacienții nedializați ($p=0,02$) (fig. 3).

Lotul dializat, conform testului Pearson, a evidențiat corelații semnificativ statistic între demența vasculară şi glicemie ($p=0,04$), respectiv depresie şi trigliceride ($p=0,04$) (tab. II).

Pe întregul lot de pacienți nivelul hemoglobinei s-a corelat cu deficitul cognitiv ($p=0,04$), aspect explicat posibil prin deficitul de vitamina B_{12} şi acid folic, ca şi cauză secundară a anemiei pacientului renal, alături de deficitul absolut sau relativ de fier, hemoliză, starea microinflamatorie, recoltări multiple, hemodializa *per se*.

TABELUL II

Corelația Pearson privind parametrii biochimici şi statusul cognitiv la lotul dializat

Statusul cognitiv	Corelația Pearson	Hemoglobina	Glicemia	Trigliceride
Disfuncție cognitivă	Total	0,151	-0,154	-0,064
	Sig. (2-tailed)	0,395	0,384	0,718
	N	34	34	34
Depresie	Total	-0,149	-0,068	**0,347***
	Sig. (2-tailed)	0,402	0,704	0,044
	N	34	34	34
Demență vasculară	Total	-0,076	**0,360***	0,218
	Sig. (2-tailed)	0,676	0,040	0,222
	N	33	33	33
*Corelația este semnificativă statistic sub nivelul 0,05 (2-tailed)				

TABELUL III

Corelația Pearson privind parametrii biochimici şi statusul cognitiv cumulativ la cele două loturi incluse în studiu

Statusul cognitiv	Corelația Pearson	Hemoglobina	Glicemia	Trigliceride
Disfuncție cognitivă	Total	**0,259***	-0,150	-0,037
	Sig. (2-tailed)	0,040	0,240	0,773
	N	63	63	63
Depresie	Total	-0,118	-0,024	**0,295***
	Sig. (2-tailed)	0,356	0,854	0,019
	N	63	63	63
Demența vasculară	Total	-0,183	0,220	0,127
	Sig. (2-tailed)	0,155	0,086	0,326
	N	62	62	62
*Corelația este semnificativă statistic sub nivelul 0,05 (2-tailed)				

De asemenea, nivelul trigliceridelor s-a corelat cu depresia (p=0,02), la fel ca şi la lotul dializat, fără a se evidenția o corelație semnificativă între statusul cognitiv şi glicemie (tab. III).

DISCUȚII

Modificările cognitive la vârstnicul cu afectare renală cronică se pot datora unor factori multipli: efectul direct al retenției azotate, nefropatia ischemică drept factor de avertizare asupra suferinței vasculare multiple, inclusiv cerebrale, tulburările asociate bolii cronice de rinichi (anemia, sindromul dislipidemic).

Mai multe studii (1, 5, 7, 9) au demonstrat afectarea diferitelor aspecte ale cogniției odată cu instalarea şi avansarea bolii cronice de rinichi, agravate odată cu inițierea metodelor de supleere renală. Date similare au fost evidențiate şi în studiu nostru, afectarea cognitivă fiind mai evidentă în lotul dializat comparativ cu cel nedializat (7,8). Urmează printr-un studiu ulterior să cercetăm şi evoluția tulburărilor cognitive după ce pacienții au fost scoşi din programul de dializă pentru a beneficia de transplantul renal. Datele existente sugerează o îmbunătățire a statusului cognitiv (3, 4, 9).

Diabetul este un factor de risc atât pentru bolile cardio-vasculare, renale cât şi

pentru cele cognitive aspect, în acord cu constatarea noastră privind unele corelații statistic semnificative între demența vasculară şi glicemie (10).

Toate aceste aspecte subliniază importanța evaluării statusului cognitiv şi al celui emoțional la pacienții vârstnici cu boală cronică de rinichi, indiferent de metoda de tratament, (supleerea renală prin dializă, inclusiv cea peritoneală sau hemodializă, tratamentul conservator sau transplant) (5, 6). De asemenea, este subliniat faptul că prezența bolii cronice de rinichi nu reprezintă o contraindicație pentru inițierea tratamentului tulburărilor cognitive, acestea având un prognostic mai bun cu cât acesta este inițiat mai devreme.

CONCLUZII

Cercetările au evidențiat că deficitul cognitiv este mai frecvent la pacientul vârstnic dializat datorită accelerării procesului de ateroscleroză, a comorbidităților (hipertensiune arterială, diabet zaharat) şi datorită asocierii în proporție ridicată a depresiei.

Nivelul hemoglobinei este corelat statistic semnificativ cu deficitul cognitiv, urmarea impactului anemiei renale cu posibilă cauză carențială secundară de vitamina B_{12} şi acid folic.

Este posibil ca pacientul nedializat să nu sesizeze deficitul cognitiv față de cel dializat, care este marcat de elementul depresiv şi care, de multe ori, ascunde deficitul cognitiv.

Este foarte importantă decelarea precoce a prezenței deficitului cognitiv la vârstnicii cu boală cronică de rinichi pentru a se iniția măsuri terapeutice adecvate ce încetinesc progresia spre demență. Prin aceste măsuri este posibil să crească perioada de independență a vârstnicului, să se amelioreze calitatea vieții şi să se reducă riscul de a dezvolta variate comorbidități.

ETIOLOGICAL ASPECTS OF ACUTE GASTROENTERITIS – A TEN-YEAR REVIEW (1.01. 2001-31.12.2010) (Abstract): Acute gastroentritis is one of the most common diseases in humans, and continues to be a significant cause of morbidity worldwide. **Aims**: To determine the bacterial pathogens associated with gastroenteritis in patients admitted to the Iasi Infectious Diseases Hospital in the last ten years. **Material and methods**: A total of 40481 stool samples were examined using conventional methods. **Results**: Bacteria were found in 7.36% of cases, and parasites in 9.64%; 83% of the cases were viral, micotic, or disbiotic. The bacterial etiology was dominated by *Salmonella spp.*(58.34%), *Shigella* spp. (27.08%) , *Yersinia enterocolitica* O3 (8.53%), *Campylobacter spp*. (1.31%), other bacterial pathogens (EPEC, *Aeromonas hydrophilla*/ *caviae*/*sobria*, *Plesiomonas shigelloides*, *Bacillus cereus*, *Staphylococcus aureus*, etc) being detected in 3.74% of the cases. Of the *Salmonella species*, group B (51.99%) followed by group D (45.23%) were most common. *Shigella sonnei* and *Shigella flexneri* were found in almost the same proportion (49.45% and 49.70%, respectively*)*; *Shigella boydii* was isolated in only 0.85% of cases. The trend of gastroenteritis caused by bacterial pathogens is decreasing: from 355 cases in 2001 to 105 cases in 2010; three peaks have been recorded in 2002, 2005 (when *Salmonella typhi* was isolated in a patient), and 2008 (469, 409, and 252 cases, respectively). Bacterial gastroenteritis affected both sexes almost equally (122 males and 118 females). The most affected age groups were: 0 – 4 years, 15 – 24 years, 5 – 14 years and 25 – 39 years. **Conclusions**: Laboratory investigations are essential in determining the etiology of gastroenteritis. Its unpredictable incidence justifies the human and material efforts aimed at controlling the spread of potentially epidemic acute gastroenteritis. **Key words:** ACUTE GASTROENTERITIS, *SALMONELLA SPP*., ETIOLOGY

Bacteriile enteropatogene sunt responsabile de un număr mare de spitalizări şi decese în lume (în SUA, anual, 46 000 spitalizări cu 1.500 decese, cel mai frecvent implicate fiind *Campylobacter*, salmonelle non-tifoidice, *E. coli* producătoare de toxina shiga şi *Shigella*) (1, 2).

Scopul acestui studiu extins pe o perioadă de 10 ani, a fost acela de a releva etiologia bolii diareice acute în dinamică şi implicit, proporţia diferiţilor agenţi etiologici implicaţi, în zona Iaşi.

MATERIAL ŞI METODĂ

Analiza retrospectivă a înregistrărilor de laborator din perioada 01.01.2001 – 31.12.2010. Studiul a cuprins 40.481 de pacienţi internaţi în Spitalul Clinic de Boli Infecţioase Iaşi, în perioada sus menţionată. Materiile fecale au fost prelevate de la toţi pacienţii în mediu de transport Cary-Blair. Examinările microscopice (citologice, parazitologice, micologice) ca şi însămânţările bacteriene s-au executat în primele 2-3 ore de la prelevarea materiilor fecale. Prelevarea, transportul, examinarea şi însămânţările bacteriene s-au executat în concordanţă cu metodele standard de laborator. Prelevatele au fost însământate pe următoarele medii de cultură: Agar desoxycholat citrat lactoză, Bulion selenit acid de sodiu, Agar Wison-Blair, Agar Mac Conkey cu sorbitol, Agar TCBS şi Agar Karmalli cu supliment selectiv. Identificarea bacteriană s-a făcut utilizând medii convenţionale de identificare pentru Enterobacteriacee şi latex aglutinare pentru identificarea speciilor patogene de Campylobacter. Identitatea speciilor bacteriene patogene, a fost confirmată de Institutul Naţional de Microbiologie şi Dezvoltare „ I. Cantacuzino" Bucureşti.

REZULTATE

Etiologia bolii diareice acute a fost în proporţie de 7,36% (2.981 cazuri) bacteriană, 9,64% (3.901 cazuri) parazitară şi în proporţie de 83% de altă etiologie(virală, micotică sau disbiotică, fiind incluse în această categorie şi cazurile la care s-a instituit tratamentul antibiotic în ambulator, diagnosticul de laborator fiind în aceste situaţii, fals negativ) (fig. 1).

Etiologia bacteriană a fost reprezentată de *Salmonella* spp. în proporţie de 58,34% (1808 cazuri), *Shigella spp*. în proporţie de 27,08% (825 cazuri), *Yersinia enterocolitica* O3 în proporţie de 8,53% (114 cazuri), *Campylobacter* spp. patogene în proporţie de 1,31% (40 cazuri), iar restul de 3,74%, alte bacterii patogene (EPEC, *Aeromonas hydrophilla*/ *caviae*/*sobria*, *Plesiomonas shigelloides*, *Bacillus cereus*, *Staphylococcus aureus* etc.). (Fig. 2) Dintre salmonele , cele din grup B au fost dominante în pro-porţie de 51,99% (992 cazuri), cele din grup D în proporţie de 45,23% (863 cazuri), grupul A, C şi E fiind mai rar izolate. (Fig. 3)

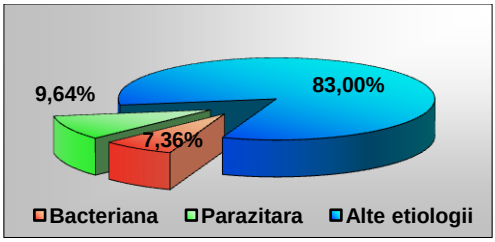

Fig. 1. Etiologia bolii diareice acute

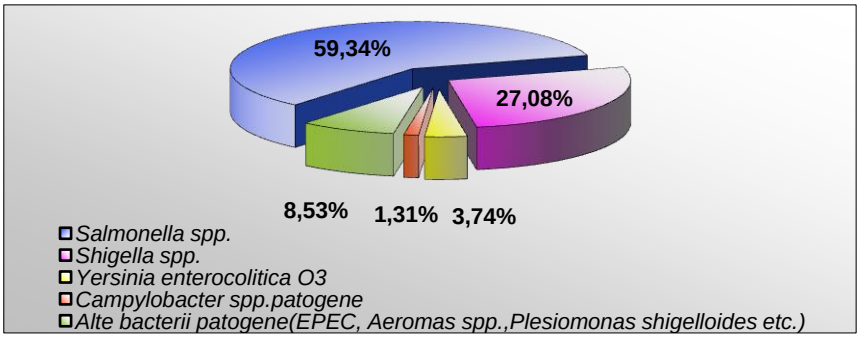

Fig. 2. Etiologia bacteriană

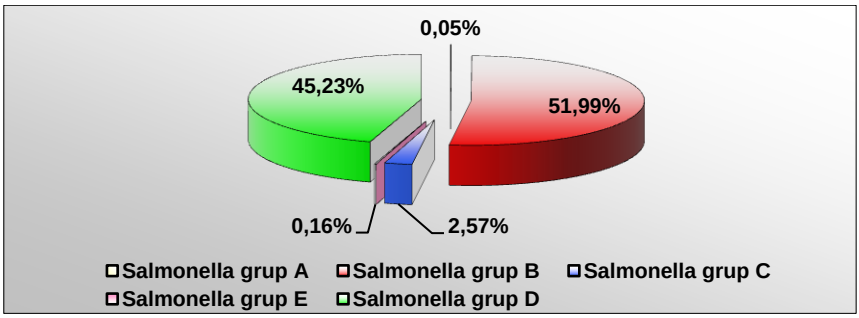

Fig. 3. Incidenţa etiologiei pe grup de salmonella

Tendinţa evolutivă a bolii diareice acute cauzată de bacterii patogene este descendentă, de la 355 cazuri în anul 2001, la 105 cazuri în anul 2010. Se remarcă totuşi trei vârfuri în anii 2002, 2005 (în acest an s-a izolat şi identificat inclusiv un caz cu *Salmonella typhi*) şi 2008 cu câte 469, 409 şi respectiv 252 de cazuri de boală diareică acută (fig. 5, 6).

Proporţia de *Shigella Sonne* şi *Shigella Flexner* a fost aproape egală, respectiv de 49,45% (408 cazuri) pentru *Shigella Sonne* şi 49,70% (410 cazuri) pentru *Shigella Flexner* iar *Shigella Boydi* a fost izolată doar în proporţie de 0,85% (7 cazuri) (fig. 4).

Incidenţa BDA de etiologie bacteriană a fost în general mai frecventă la sexul masculin, incidenţa medie în cei 10 ani studiaţi fiind de 122 de cazuri la sexul masculin şi 118 cazuri la sexul feminin (fig. 7).

Grupele de vârstă cele mai afectate au fost grupa 0 – 4 ani,15 – 24 ani, 5 – 14 ani şi 25 – 39 ani, cele mai puţine cazuri înregistrându-se la vârsta de peste 80 ani , la grupa 60 – 79 de ani şi la grupa 40 – 59 ani (fig. 8).

DISCUŢII

Transmiterea bolii diareice se produce în proporţie de 80% cazuri prin intermediul alimentelor. Transmiterea interumană este posibilă pentru agenţii infecţioşi cu doză infectantă mică: *Shigella, E coli* producătoare de toxina shiga, protozoare şi virusuri. Clinicianul ar trebui să ia în consideraţie agenţii etiologici posibili în funcţie de tabloul clinic. Când se suspectează o bacterie enteropatogenă, examenul bacteriologic al materiilof fecale şi cercetarea toxinelor contribuie în mod crucial la stabilirea diagnosticului de certitudine. Majoritatea laboratoarelor sunt dotate pentru cercetarea de rutină a shigellelor, salmonellelor şi *Campylobacter* în coprocultură. Pentru diareea cu sânge, laboratorul ar trebui dirijat către determinarea *E coli* producătoare de toxina shiga. În diarrea asociată cu alimente marine sau de tip holeriform, ar trebui cercetaţi vibrionii holerici sau non-holerici. Indicaţiile coproculturii includ diareea severă (emisia de cel puţin 6 scaune pe zi), diareea persistentă peste 7 zile, febra, dizenteria sau o izbucnire epidemică. Coprocultura nu se recomandă în diareea apoasă sau diareea călătorului din cauza posibilităţilor etiologice restrânse. O singură coprocultură ar trebui să fie suficientă pentru un laborator competent (3).

Diareea bacteriană se poate asocia cu o serie de condiţii clinico-epidemiologice. Diareea acută apoasă este dată în principal dată de *Salmonella* şi *Campylobacter*, dar şi de *E coli* enterotoxigen, enteroagregant sau enteroinvaziv, vibrioni non-holerici sau norovirusuri (4). Tabloul clinic de dizenterie poate fi dat de *Shigella, Campylobacter*, salmonelle non-tifoidice şi *E coli* producătoare de toxina shiga, dar şi de *Aeromonas*, vibrioni non-holerici sau *Yersinia enterocolitica* (5). Toxiinfecţiile alimentare sunt date în principal de *S. aureus* şi de *C perfringens*. Diareea călătorului poate fi dată de *E coli, Shigella, Salmonella, Campylobacter, Aeromonas,* vibrioni non-holerici sau *Plesiomonas*. Diareea nosocomială este asociată cu *C difficile.*

Incidenţa mare a bolii diareice ridică o serie de probleme: transmiterea germenilor prin alimente într-o societate de consum şi o piaţă globală menţine posibilitatea unei morbidităţi şi mortalităţi ce pot deveni la un moment dat catastrofale (6). Susceptibilitatea la boala diareică (inclusiv factorii genetici şi microbiota intestinală), nu este pe deplin cunoscută (7). Factorii care influenţează riscul complicaţiilor pe termen mediu sau lung (deshidratarea, bacteriemia, sindromul hemolitic-uremic, sindromul Guillain-Barre, artrită sau irită reactivă, sindromul postinfecţios de intestin iritabil), nu au fost încă stabiliţi (1).

CONCLUZII

Investigaţiile de laborator (bacteriologice, virologice, micologice) sunt indispensabile stabilirii etiologiei bolii diareice acute şi instituirii terapiei adecvate. Incidenţa imprevizibilă justifică eforturile materiale şi umane angajate în limitarea extinderii bolii diareice acute cu potenţial epidemic şi pentru spitalele de boli infecţioase cea mai bună strategie este aceea de „expectativă armată”.

NOUTĂȚI

NOI DIRECȚII TERAPEUTICE ÎN NEFROPATIA INDUSĂ DE CYCLOSPORINA A

Activarea sistemului renină angiotensină aldosteron (SRAA) joacă un rol important în nefropatia indusă de cyclosporina A. Scopul acestui studiu este de a demonstra că administrarea de extract de ceai verde poate preveni apariţia acestui tip de nefropatie. Pentru acest studiu au fost folositi şobolani care au fost împărţiţi în patru grupuri (6 în fiecare grup) şi trataţi 21 de zile: un grup de control (grupul 1) cărora li s-a administrat ser fiziologic, grupului 2 doar cyclosporină intraperitoneal 30 mg/kg/zi, grupului 3 cyclosporină şi extract de ceia verde 100 mg/kg/zi subcutanat iar grupului 4 doar extract de ceai verde. S-au observat niveluri plasmatice crescute de uree şi creatinină în grupul 2 comparativ cu grupul 3 şi cu grupul 1. Analizele biochimice au arătat că activitatea plasmatică a reninei şi concentraţia serică a aldosteronului au fost semnificativ crescute în grupul 2 faţă de grupul 1 şi semnificativ scăzute în grupul 3 faţă de grupul 2. Astfel, s-a demonstrat că administrarea cyclosporinei creşte nivelurile intrarenale ale reninei şi induce nefrotoxicitate. Efectele protective ale extractului de ceai verde în ceea ce priveşte nefropatia indusă de cyclosporină pot consta în blocarea SRAA. (Hyun HR, Hyun LK, Chung JH et al. Renoprotective effects of green tea extract on renin-angiotensin-aldosterone system in chronic cyclosporine-treated rats. *NephrolDial Transplant*. 2011; 26: 188-1193).

EFFICACY OF *HELICOBACTER PYLORI* ERADICATION THERAPY IN CIRRHOTIC PATIENTS WITH PEPTIC ULCER DISEASE. (Abstract). Few studies have been focused on the role of *Helicobacter pylori* eradication in cirrhotic patients with peptic ulcer and the reported results are conflicting. **Aim:** To evaluate the efficacy of proton pump inhibitor (PPI)- based triple therapy on peptic ulcer course in patients with liver cirrhosis. **Material and methods:** This prospective study was carried out in a tertiary-care hospital. Of the 63 consecutive cirrhotic patients with peptic ulcer identified by endoscopy 39 (22 males, 14 females, aged 53 to 62 years) entered the study. The patients with peptic ulcer and *H. pylori* infection received eradication therapy, while *H. pylori negative* patients received PPI treatment. *H. pylori* eradication was confirmed by rapid urease test and histological examination. Follow-up endoscopies were performed at 6 and 12 months. The patients with peptic ulcer recurrence were treated with PPI. **Results:** Of the 39 selected patients 22 (56.4%) were *H. pylori* positive, and 17 (43.6%) were *H. pylori* negative. *H. pylori* was eradicated in 63.6% (14/22) of the patients. During the follow-up period 2 *H. pylori* negative patients died from variceal bleeding and hepatic encephalopathy, respectively, and one *H. pylori* positive patient did not return for further assessment). Ulcers recurring within 1 year were found in 14 of 36 (38.8%) patients. Peptic ulcer recurred in 4 of 21 (19.0%) *H. pylori* positive patients and in 10 of 15 (47.6%) *H. pylori* negative patients at study entry. Patients' age (p=0.018), Child-Pugh stage (p=0.019), peptic ulcer site (p=0.008), and *H. pylori* negative status (p=0.004) were significantly related to ulcer recurrence. **Conclusions:** Eradication of *H. pylori* infection in patients with liver cirrhosis and peptic ulcer disease could be helpful, but does not protect all cirrhotic patients from peptic ulcer recurrence. Most relapsed ulcers were gastric ulcers in *H. pylori* negative patients. **Key words:** PEPTIC ULCER, *HELICOBACTER PYLORI* ERADICATION, LIVER CIRRHOSIS

Peptic ulcer is a major problem in patients with liver cirrhosis and the risk of peptic ulcer is greater in these patients. (1). Factors related to peptic ulcer occurrence and the causes of the increased prevalence of the disease in cirrhotic patients are still poorly defined. Hypergastrinemia, a decrease in gastric prostaglandin E2 levels, portosystemic shunting allowing the ulcerogenic factors to escape hepatic clearance, an impairment of gastric mucosal defense secondary to portal hypertension and congestive gastropathy, alterations in gastric acid secretions have been postulated (2, 3).

In particular, the role of *H. pylori* in determining peptic ulcer disease in liver cirrhosis remains controversial; many studies have found no relationship between the two diseases, but others suggested that peptic ulcer disease is firmly linked to the *H. pylori* infection (4,5,6). It is well known that the eradication of *H. pylori* infection markedly decreases peptic ulcer recurrence in non-cirrhotic patients (7). Current strategies for the cure of *H. pylori* infection include triple therapy with a PPI, amoxicillin and clarithromycin or metronidazole (8). Moreover, eradication of *H. pylori* infection also decreases the risk of recurrence in patients with bleeding peptic ulcer (9). However, the role of *H. pylori* eradication in the course of peptic ulcer disease in patients with cirrhosis needs to be clarified. Therefore, an understanding of the determinants of the success or failure of attempts to cure *H. pylori* infection with triple therapy is clinically important in cirrhotic patients (10).

The aim of the present study is to assess the effects of *H. pylori* eradication in cirrhotic patients with peptic ulcer endoscopically detected during one-year follow-up period.

PATIENTS AND METHODS

From January 2006 to January 2011, 63 consecutive cirrhotic patients with peptic ulcer admitted at the Institute of Gastroenterology and Hepatology from Iaşi underwent to endoscopic examination in order to detect the presence of gastroesophageal varices or to investigate epigastric pain or unexplained anemia.

Patients with a history of malignancy, gastric surgery, *H. pylori* eradication, presence of significant comorbidities, active variceal bleeding, hepatic encephalopathy and those who had taken PPIs, antibiotics, bismuth compounds and/or non-steroidal anti-inflammatory drugs four weeks before endoscopy were excluded from the study.

Liver cirrhosis was diagnosed using a combination of clinical, biochemical and imagistic methods. The severity of cirrhosis was scored according to the Child-Pugh classification. The etiology of cirrhosis was defined as alcoholic, if viral markers (HBs Ag, anti-HCV) were negative and there was a history of ethanol intake of over 60 g/day for 5 years or more or viral in the presence of chronic viral infection markers.

The protocol of the study was approved by the Ethical Committee of our hospital and informed consent was obtained from all patients.

Endoscopy was performed using an Olympus GIF 240 videoendoscope. Endoscopic diagnosis of peptic ulcer disease was made when a distinct ulcer crater with fibrin-coated base larger than 5 mm was observed. The diagnosis of benign gastric ulcer was always confirmed by multiple biopsies of the ulcer.

Two biopsy specimens (one from the gastric antrum and one from the gastric corpus) were obtained to identify *H. pylori*, using the rapid urease test (CLO test) and histological examination (modified Giemsa). Results positive for *H.pylori* were defined as both a positive urease test and a typical microscopic appearance.

Enrolled patients were treated according to their *H. pylori* status: *H. pylori* positive patients received a triple therapy regimen that included omeprazole (standard dose, b.d.) combined with amoxicillin (1,0 g b.d.) and clarythromycin (500 mg b.d.) for 1 week, followed by a PPI 20 mg daily for 3 more weeks (if they were diagnosed with duodenal ulcer) or for 7 more weeks (if they were diagnosed with gastric ulcer); *H.*

pylori negative patients with duodenal or gastric ulcer received omeprazole 20 mg daily for 4, respectively 8 weeks. All patients had a second endoscopy at least 4 weeks after eradication treatment completion to assess ulcer healing and *H. pylori* status with rapid urease test and histology. *H. pylori* was considered eradicated if both rapid urease test and histologic examination results were negative. Patients with healed ulcer entered the follow-up period irrespectively of their *H. pylori* status.

Patients with unhealed ulcer were treated with a PPI 20 mg daily for a period of 4 weeks (duodenal ulcer) and 8 weeks (gastric ulcer). A new endoscopy was performed at the end of the therapy. Patients with complete ulcer healing were included in the follow-up period.

Clinical evaluations were performed monthly. Adverse effects of the therapy or symptoms indicating peptic ulcer recurrence were evaluated. The first follow-up endoscopy was performed at 6 months and the second at 12 months or earlier if they accused epigastric pain or other symptoms at any time during the follow-up. Recurrent ulcers were defined as the reappearance of ulcers during endoscopic examinations within 6 months after healing of index ulcers. Drug therapy for recurrent ulcers consisted of 20 mg PPI daily was given for 8 weeks.

Statistical analysis

Descriptive statistical values were expressed as number (%) for categorical data or median (range) for continuous data. Quantitative variables were compared according to the Student t test and qualitative variables were compared by using the chi-square test. A p-value of less than 0.05 was considered statistically significant.

RESULTS

During the study period, 63 cirrhotic patients with peptic ulcer were screened. Twenty- four patients were excluded from the study because of systematic use of PPI within one month before endoscopy (N=7), use NSAID within one month before endoscopy (6), hepatic encephalopathy (N=5), active variceal bleeding (N=5), hepatocellular carcinoma (N=1).

Finally, 39 patients (25 male, 14 female, aged 47 to 63 years) with liver cirrhosis and peptic ulcer were enrolled in the study (Table 1). Their demographic characteristics and endoscopic findings are shown in Table I.

TABLE I

Demographic and clinical characteristics and endoscopic findings

	N = 39
Sex	
Male	25 (64.1 %)
Female	14 (35.9 %)
Age (median, range)	54 (47-63 years)
Child-Pugh class	
A	11 (28.2 %)
B	14 (35.9 %)
C	11 (35.9 %)
Etiology of liver cirrhosis	
Alcohol	17 (43.6 %)
HBV	6 (15,3 %)
HCV	16 (41.1 %)
Peptic ulcer site	
Duodenal	16 (41.1 %)
Gastric	23 (58.9 %)
H. pylori status	
Positive	22 (56.4 %)
Negative	17 (43.6 %)
Esophageal varices	
Yes	31 (79.5 %)
No	8 (20.5 %)
Portal gastropathy	
Yes	15 (38.4 %)
No	24 (61.6 %)

Among the 39 eligible patients, 22 patients (56.41%) were *H. pylori* positive and 17 patients (43.59%) were *H. pylori* negative on enrollment. Successful *H. pylori* eradication rate was 63.6% (14/22).

Eight patients (3 diagnosed with gastric ulcer and 5 with duodenal ulcer) with persistent *H. pylori* infection entered the follow-up period without receiving a second course of *H. pylori* eradication regimen.

Nine patients (40.9%) reported mild adverse effects included bitterness of taste and abdominal discomfort. However, the eradication therapy was considered safe since no serious side effects were identified during treatment.

Peptic ulcer was healed in 15/22 (68.2%) *H. pylori* positive patients. Patients with unhealed ulcer were treated with a PPI 20 mg twice daily; finally, they achieved ulcer healing after another 8 weeks of therapy.

Ulcer healing rate was higher in patients who achieved eradication than those who remained *H. pylori* positive, but these differences were not statistically significant (p=0.699) (Table II).

Among the 17 patients with *H. pylori* negative ulcers, peptic ulcer healing was found in 10 (58.8%) patients after 4 weeks of PPI 20 mg once per day treatment and the other 7 patients were cured after 8 weeks of PPI 20 mg once per day treatment.

TABLE II

Ulcer healing rate according to *H. pylori* eradication

Healed ulcer	N=15	*H. pylori* eradicated N=10 (66,7%)	*H. pylori* positive persistently N=5 (33.3 %)	p-value
Gastric ulcer	5	3 (60.0 %)	2 (40.0 %)	$\chi^2 = 0.15$
Duodenal ulcer	10	7 (70.0 %)	3 (30.0 %)	p = 0.699 (NS)

During the follow-up period, 3 patients were excluded from the study (2 patients *H. pylori* negative died from active variceal bleeding and hepatic encephalopathy, respectively and one patient *H. pylori* positive did not return for further evaluation).

Thirty-six patients (22 male, 14 female, aged 53 to 62 years) entered the follow-up period; peptic ulcer healing was noted in all patients, but 8 patients remained *H. pylori* positive despite of eradication therapy.

Recurrent peptic ulcers (12 gastric ulcers, 2 duodenal ulcers) within 1 year were found in 14 patients (38.88%).

Peptic ulcer recurrence was observed in 2 of 13 patients (15.4%) who had *H. pylori* eradicated and in 2 of 8 patients who remained *H. pylori* positive (25.0%). The ulcer recurrence did not differ in patients with liver cirrhosis whether *H. pylori* infection was present or not (p = 0.297) (Table III). Epigastric pain was noted in one patient, 3 of them were asymptomatics.

TABLE II

Ulcer recurrence rate according to *H. pylori* eradication

Reccurence	**Eradication rate**	
	Eradication	**Noneradication**
Yes N=4	2 (50.0%)	2 (50.0%)
No N=17	11 (64.7%)	6 (35.3%)
	$\chi^2 = 0,297$ p = 0,586 (NS)	

Among the 15 patients with *H. pylori* negative peptic ulcer, the recurrence was found in 10 (9 gastric ulcer, 1 duodenal ulcer) patients (66.6%).

Table IV compares baseline characteristics of patients with or without ulcer recurrence during the follow-up period.

The univariate analysis showed that patient's age (p = 0.018), severity of cirrhosis (p=0.019) (figure 1), peptic ulcer site (p = 0.008) (figure 2) and *H. pylori* negative status (p = 0.004) (figure 3) were significantly related to ulcer recurrence.

Moreover, the frequency of relapsers was increased in the presence of portal gastropathy (p = 0.016). Peptic ulcer recurrence was not related to gender or to etiology of liver cirrhosis. There were no complications during the follow-up period: this could be due to the regular timing of endoscopy which permitted early detection and treatment of the recurrence.

TABLE IV

Recurrence of peptic ulcer according to the characteristics of the patients who were included in follow-up period

	(N = 36)	**Ulcer recurrence (N = 14)**	**No ulcer recurrence (N = 22)**	**p-value**
Sex				
Male	22 (61.10 %)	10 (71.40 %)	12 (54.50 %)	0.311 (NS)

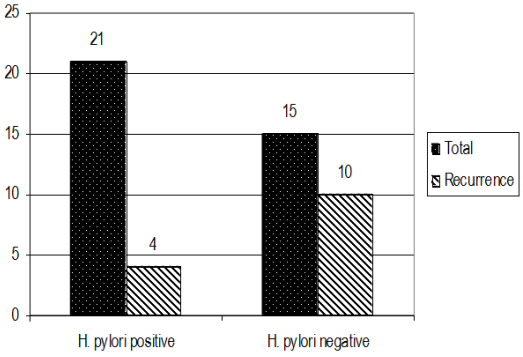

Fig. 3. Peptic ulcer recurrence according to *H. pylori* status (p<0.05)

DISCUSSION

Few data about *H. pylori* eradication and the clinical course of peptic ulcer in cirrhotic patients are avaible. Since most of patients with chronic liver disease required treatment with many drugs and the concentrations of the active metabolite of clarithromycin were found to be lower in patients with hepatic impairment, it could be difficult to choose a proper regimen for *H. pylori* eradication (11).

It is well known that eradication of *H. pylori* infection markedly changes the natural history of peptic ulcer in patients with duodenal or gastric ulcer and normal liver function. (12). In these patients, peptic ulcer recurrence can be greatly reduced from 60%-70% to 0%-10% when *H. pylori* is eradicated (7).

The impact of *H. pylori* on the recurrence of peptic ulcers in patients with cirrhosis is still uncertain. To our knowledge, the effects of *H. pylori* eradication on the recurrence of peptic ulcers among patients with cirrhosis have been investigated in only two studies (2, 9).

A recent publication from Greece reported peptic ulcer recurrence rate 41 % after successful eradication treatment and eradicated *H. pylori* infection was related with longer peptic ulcer relapse-free time. Recurrence rate was 90% (9 of 10 patients) in *H. pylori* negative patients and 44.4% (8 of 18 patients) in *H. pylori* positive patients at study entry. This peptic ulcer relapse rate is much higher as compared with that observed in the general population and could be explained by a long term of follow-up (2 years) and different course of peptic ulcer in cirrhotic patients. Another notable finding was that maintenance treatment with a PPI can effectively protect cirrhotic patients from ulcer recurrence and its complications (9).

Lo et al. detected duodenal ulcer recurrence rates 58% (21 of 36 patients) after successful *H. pylori* eradication therapy, 44% (8 of 18 patients) after failure of *H. pylori* eradication and 48% (24 of 50 patients) in *H. pylori* negative patients during 1 year of follow-up. So, the authors suggested that the policy of testing and eradication of *H pylori* universally is questionable in patients with cirrhosis and duodenal ulcers. It was also identified a statistically significant association of duodenal ulcer recurrence with the presence of portal gastropathy and the history of variceal bleeding. (2).

Our data showed that over the study period, ulcer recurrence in *H. pylori* positive cirrhotic patients was 19.0% (4/21); the ulcer recurrence did not differ in patients with liver cirrhosis whether *H. pylori* infection was present or not. We can conclude that eradication therapy does not protect all cirrhotic patients from peptic ulcer recurrence. According to our results, a subgroup of *H. pylori* positive patients may benefit from eradication therapy. Indeed, peptic ulcer relapsed in 15.4% of our patients after successful *H. pylori* eradication. Moreover, the ulcer recurrence in *H. pylori* positive patients was significantly lower than in *H. pylori* negative patients ($p = 0.04$). A strong correlation between ulcer recurrence and peptic ulcer site has been shown (gastric ulcer vs. duodenal ulcer = 85.7% vs. 13.4%, $p = 0.008$). Interestingly, we also found that the presence of portal gastropathy did seem to predispose to ulcer recurrence ($p = 0.016$). In addition, we identified a statistically significant association of ulcer recurrence with advanced stages of cirrhosis ($p = 0.019$). This agrees with a previous report demonstrating a shorter ulcer relapse-free time in patients

with Child B and C (9). Taken together, the pathogenetic mechanisms of peptic ulcer disease in cirrhotic patients appear multifactorial and are far from being elucidated.

In conclusion, eradication of *H. pylori* infection could be helpful, but does not protect all cirrhotic patients from the recurrence of peptic ulcers. Other factors than *H. pylori* could play a key role on peptic ulcer recurrence in cirrhosis such as advanced age, portal gastropathy and progression of liver disease.

TESTING AND VALIDATION OF A NEW METHOD FOR THE INVESTIGATION OF FUNCTIONAL CHANGES IN HUMAN HEART AND SKELETAL MUSCLES (Abstract): **Aim**: Analysis of the efficiency of the use of permeabilized fiber in clinical medicine. **Material and methods**: Mitochondrial respiration was performed in 680 patients with dilated cardiomyopathy (DCM), hypertrophic cardiomyopathy (HCM), inflammatory cardiomyopathy (ICM) and ischemic heart disease/Ischemic cardiomyopathy (IHD/Ischemic CM) with heart failure (HF) 0-IY NYHA, as well as in the deltoid muscle during fitness in athletes. Subendomycocardial and deltoid muscle biopsy, myocardial scintigraphy, quantitative immunoblotting and electrophoresis were performed. **Results**: Scintigraphy revealed left ventricular (LV) perfusion defects of 85.6% in Ischemic CM/IHD and 81% in DCM. The indices of myocardial hypertrophy showed a 42% increase in tubulin and 33% increase in desmin levels, and of skeletal myosin beta isoforms by 20%. SM22 was increased 1.5-fold, Kinase Related protein KRP by 52%, Myosin Light Chain Kinase (MLCK) by 70%. Nuclei were bizarre and oversized. CrKmit fraction - 12.8, MB - 27.24, in the intact myocardium, 21.08 and 19.7, respectively. Mitochondrial respiration, Vmax / Vo 2.27 ± 0.17 1.52 ± 0.08 <0.001. Tissue respiration of the deltoid muscle in athletes correlated with the amount and density of mitochondria and was related to the level of physical fitness. **Conclusions:** The study shows that the use of this method of approaching and interpreting the data obtained through the permeabilized cell technique, largely based on personal clinical results, makes it possible to identify the earliest mitochondrial functional changes and their consequences on the energy balance and mechanical function of the heart, thus validating the method as a reference in the investigation of various cardiac diseases and assessment of skeletal tissue capacity related to fitness level. **Keywords:** CARDIOMYOCYTE, MITOCHONDRIA, MITOCHONDRIAL RESPIRATION, ISCHEMIA, CARDIAC INSUFFICIENCY, CARDIOMYOPATHY.

The considerable advances in recent years in the fields of molecular biology and medical imaging in heart disease have led to the identification of new entities by a

better understanding of the mechanisms and causes of intrinsic and secondary myocardial diseases. The latest classification proposed by the American Heart Association (AHA) in 2006, reiterated and commented by the European Society of Cardiology (ESC) in 2008, is based on a more thorough understanding of molecular aspects and mutations in myocardial proteins. An imperative of this is the study of the mechanism of mitochondrial oxidative phosphorylation, ATP production and the modalities of intracellular transport of energy from mitochondria to its sites of use, in myofibrils, by phosphocreatine molecules, through the various creatine kinase isoferments. The method of recording the respiratory rate through the isolated mitochondria technique, which until recently has been used as a single procedure requires large amounts of muscle tissue (50-60 grams wet weight), making it inapplicable under clinical conditions, especially in cardiology. Recently, a new method for the study of mitochondrial function has been proposed (3) using saponin-permeabilized muscle fibers. On extremely small pieces of tissue, this technique offers the possibility of precisely controlling the extramitochondrial environment and the properties of mitochondria, which in isolation conditions may be lost. We are the first to use this method for more than two decades in the study the mitochondrial function, especially in clinical heart diseases and skeletal muscles.

MATERIAL AND METHODS

Prospective study on mitochondrial respiration, determined in 680 patients with circulatory insufficiency, stages 0-IY according to NYHA classification in various pathological conditions: dilated, hypertrophic, inflammatory, and ischemic cardiomyopathy; decompensated hypertrophy; coronary circulation and various forms of hemodynamic and intramyocardial disorders, in total – 655 patients; in acute myocardial ischemic injury during open heart surgery and in heart preservation problems – 25 patients with acquired heart defects, as well as the assessment of mitochondrial respiration in the deltoid muscle during exercise – 30 athletes. The control group consisted of 120 healthy individuals. Cardiac catheterization, coronaroventriculography, subendomycocardial and deltoid muscle biopsy, electron and confocal microscopy, myocardial scintigraphy, quantitative immunoblotting and electrophoresis were performed.

RESULTS

The coronarography study in DCM patients highlighted large, sinuous coronary arteries of typological significance. The passage of the contrast medium and its subsequent wash-out, both in the large arterial trunks and in third- and fourth-order arteries were slowed down. In patients with DCM and Ischemic CM the diameter of the coronary arteries in systole and diastole was significantly higher and the extensibility index was lower than in the control group. No clear index differences were noted between DCM and Ischemic CM patients, except for the diastolic diameter of the right descending coronary artery.

Positron emission computed tomography with TL-201 detected LV myocardial perfusion defects in DCM (81.1%), Ischemic CM (82.5%), and in 100% of ICM cases, the incidence of perfusion defects occupying over 20% of LV area; in DCM it was 35.2%, in Ischemic CM - 45.5%, and

in ICM - 69.5%. In 75% of the cases perfusion defects coincided with the localization of myocardial scarring changes, according to the data of instrumental investigation, ECG, ECOCG, CVG, necropsy, in Ischemic CM patients (tab. I).

TABLE I

Comparison of left ventricular myocardial infarction defect sizes in patients with Ischemic CM and DCM according to myocardial scintigraphy with TI-201 at rest

	Perfusion defects (% of LV area)			
	total per group	IC I-II (NYHA)	IC III-IV (NYHA)	P
DCM	n = 71 13,7 ± 1,3	n = 49 13,1 ± 1,6	n = 22 15,1 ± 2,3	NS
Ischemic CM /IHD	n = 63 14,2 ± 1,7	n = 28 9,5 ± 2,0	n = 35 17,7 ± 2,4	< 0,02
Accuracy of P differences	1-3 < 0,002 2-3 < 0,001 1-2 – NS	1-3 < 0,01 2-3 < 0,002 1-2 – NS	NS	

Expression of protein markers of myocardial hypertrophy in DCM showed an increase in tubulin level on average by 42%, in desmin by 33% and in skeletal myosin beta-isoform by 20%, in smooth muscle proteins, alpha-smooth muscle actin and SM22 (1,5-fold), KRP by 52%, MLCK by 70%, MHCβ by 21%. *The morphometric study* showed bizarre and oversized nuclei with highly elevated levels of membrane convolutions. *Electrophoretic analysis* of the total creatine kinase fraction revealed significant alterations in the expression of creatine kinase isoenzymes. The diseased myocardium had a lower mean creatine kinase content and a higher MB content compared to the healthy myocardium (fig. 1).

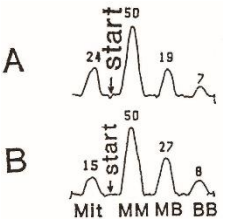

Fig. 1. Spectrum of creatine kinase isoenzyme in normal human myocardium (A) and cardiomyopathic myocardium (B).

In athletes there was a quantitative increase in mitochondrial density with a significant increase in mitochondrial respiratory capacity related to physical fitness level.

The increased cardiomyocyte mitochondrial respiration rate (Δ%) by the stimulation of *ADP* and creatine in patients with DCM HF-III-IV (NYHA) is certainly lower than that in those with HF-I-II (NYHA), demonstrating a more pronounced myocardial hypoxia in the patients with severe cardiac functional and morphological changes (tab. II).

Evaluation of mitochondrial status and efficacy of mitochondrial creatine kinase function in ischemia and after reperfusion during the surgical correction of acquired cardiac defects revealed have significant changes. More prominent was the three-fold increase of creatine-stimulated respiration, which demonstrates alteration of the mitochondrial creatine kinase system. These changes are reversible after reperfusion in the presence of phosphocreatine.

TABLE II

Indices of cardiomyocyte mitochondrial respiration in patients with DCM depending on heart failure stage

	HF – III (NYHA)	*HF* – IV (NYHA)	Accuracy of differences P
Basal mitochondrial respiration rate Vo ng atom O/min/mg dry weight	1,91 ± 0,29	3,86 ± 0,23	< 0,001

Vmax / Vo	2,27 ± 0,17	1,52 ± 0,08	< 0,001

DISCUSSION

The success of models used to study differentiated complexity should be understood sequentially when applied to sufficiently large domains (1,2).

The topic that we have assumed as a sphere of interest and an object of a long-lasting study is mitochondrial respiration, a new method for the investigation of functional changes in human heart and skeletal muscles. By means of relating the subject to the whole issue, as well as to its structural connections with other adjacent problems, we are aimed at highlighting, with the help of combining the descriptive method with analytical and interpretative ones, the rich diversity and complexity of the topic which seems to us extremely important because of its considerable scientific and moral significance.

The permeabilized fiber method (3), used by us, proved to be very well suited to studying the functioning of mitochondria in patients with DCM, ICM and Ischemic CM; in decompensated cardiac hypertrophy; in acute myocardial ischemic injury and in heart preservation-related issues, as well as in the assessment of deltoid muscle mitochondrial respiration during physical fitness in athletes (4-8). In the latter, in addition to the stimulation of mitochondrial quantitative growth and density, training improves mitochondrial qualities as shown by physical fitness-related increase in mitochondrial respiration. Higher oxygen extraction in the working muscle reduces glycolysis and the

use of glycogen with the increase of aerobic resynthesize of ATP during exercise, decisive for delaying fatigue and ensuring performance. Mitochondrial function declines with age and may contribute to the loss of muscle strength and cardiorespiratory endurance. Lower mitochondrial capacity and efficacy are associated with a lower walking speed. At the same time, older adults who maintain a high level of physical activity have a greater mitochondrial capacity, like that of the very active young adults (9, 10). This suggests that by the assessment of the bioenergetic status mitochondria may be determinant in predicting performance in certain physical fitness situations, and an important therapeutic target for sedentary lifestyle- and aging-related conditions including sarcopenia, dynapenia and loss of physical function (11, 12). In most of the patients with primary myocardial diseases investigated by us there were coronary and/or intracardiac circulation disorders which confirmed the presence of chronic myocardial hypoxia and its role in primary and/or secondary cardiomyocyte injury. An evidence of this is also the cardiomyocyte mitochondrial respiration rate (Δ%) by stimulation of ADP and creatine in patients with HF-III-IV NYHA and in those with more marked cardiomyocyte hypertrophy and bizarre nuclei, which is certainly lower than in HF-I-II NYHA, Vmax / Vo 2.27 ± 0.17 1.52 ± 0.08 < 0.001. In the ischemic heart, the fastest cellular change is mitochondrial swelling which causes the disruption of the outer mitochondrial membrane or the dissociation of creatine kinase from the inner mitochondrial membrane. The lesion effect on the membrane is mainly exerted by lysophosphatidic which increase ischemic cardiomyocytes. Phosphocreatine completely inhibits the elevation of lysophosphatidylcholine and lysophosphatidylethanolamine in the sarcolemma membrane of the ischemic myocardium which may be one of the possible mechanisms that protect the adjacent membrane of contractile cardiomyocytes adjacent to phosphocreatine. For this reason, creatine-stimulated respiration is a very sensitive indicator of ischemic disease and, at the same time, of the efficacy of heart protection in heart conditions. The study of the aspects of myocardial morphological alterations in patients with cardiomyopathy and measured cellular creatine kinase function revealed low PCr/ ATP ratio only in DCM patients with severe heart failure due to insufficient ATP formation. To the same extent, the reduced mitochondrial creatine kinase function can be combined with low myofibrillar activity of ATPase in the diseased heart (5, 6). This assumption is confirmed by the decrease by up to 57% of creatine content in the DCM patients with severe heart failure and pronounced cardiomyocyte hypertrophy. The increase of end-diastolic pressure in our DCM patients can be largely related to the increase in myofibrillar ADP due to its reduced rephosphorylation resulting from the decreased efficiency of phosphocreatine pathway for energy transport. ADP in excess amounts is sufficiently tightly bound to myosin with the concomitant inhibition of ATPase activity and dissociation of cross-bridges. This may be the cause of the increase of end-diastolic pressure and decrease of ejection fraction in DCM patients with severe heart failure and pronounced hypertrophy, with larger cardiomyocyte nuclei of unusual shapes.

CONCLUSIONS

Our study demonstrates that the use of this method of approaching and interpreting the data obtained through the permeabilized cell technique, largely based on

personal clinical results, makes it possible to identify the earliest mitochondrial functional changes and their consequences on the energy balance and mechanical function of the heart, thus validating the method as a reference in the investigation of various cardiac diseases and assessment of skeletal tissue capacity related to fitness level.

THE ROLE OF REAL - TIME ELASTOGRAPHY IN THE EVALUATION OF POST CHEMOTHERAPY HEPATHOTOXICITY IN CHILDREN WITH CANCER (Abstract) : The drugs hepatotoxicity represents a major problem of the iatrogenic pathology, with various manifestations, directly through the hepatotoxic effect or through idiosycrasy reactions. The hepatic affection induced by chemotherapy appears in children in cases of prolonged therapy, chronic diseases, or other associated conditions. Hepatotoxicity clinically develops through hepatic disorder, cholestatic or mixed hepato-cholestatic manifestations and systematic affection. There are no specific hystological or biochemical characteristics for diagnostic of hepatotoxicity. The international criteria for asessing the hepatotoxicity includes the bilirubin, the transaminasis, GGT, FA, albumin and the flow on the vein. It has been noticed that these parameters are not enough for the right assesssment of the chemotherapics' hepatotoxicity. Thus it is required the abdominal ultrasonography and computerised tomography for the identification of billiary tract, vascularisation, associated conditions and the degree of fibrosis ; also, the hepatic biopsy may be necessary. The ultrasound elastography is a method which can give information related to the elasticity/stiffness of the examined tissue and degree of fibrosis. Acustic radiation force imaging(ARFI) is an elastographic method which allows valid, accurate and flexible evaluation of liver stiffness, a quantification with a strong correlation with the fibrosis stage, not influenced by steatosis. In conclusion, the hepatic toxicity showed by alterated hepatic biochemical tests and by symptomes of hepatopathy needs a proper appreciation of the hepatic modifications, which can be obtained through hepatic biopsy or by assessing the hepatic elasticity through elastography. Thus, real-time elastography is an useful tool in assessing the chemotherapics hepatotoxicity in children with cancer. **Key words** : ELASTOGRAPHY, HEPATOTOXICITY, CANCER

The drugs hepatotoxicity represents a major problem of the iatrogenic pathology, because of a great increase of the number of drugs with toxic action on liver, and also the fact that the drug hepatopathology includes various clinic, biological and histological manifestations which can get the aspect of any kind of hepatobilliary disease, acute or chronic, and histologically necrosis, steatosis, fibrosis and vascular injury (1, 2, 3).

The hepatic toxins can lead in a great number of cases to hepatic fulminating, di-

rectly through the hepatotoxic effect or through idiosycrasy reactions (4).

Chimiotherapies against cancer, known as oncostatic agents, drugs against tumours, cytostatics are substances capable to improve the clinic condition, to decrease the tumour volume, to prolong the surviving period and sometimes to heal the patients with cancer affections, on the other hand the main effect of the oncostatic agents is cytotoxicity beside one or more aimed organs. (5)

The cytostatic treatment inevitably affects the liver, which is one of the tissues with the most intensive metabolic activity of the organism. In normal condition these effects are clinically unseen because of the liver's capacity of regeneration. Though the hepatic affection induced by chemotherapy appears more often in children in cases of prolonged therapy, debilitated chronic diseases, immunosupresion, viral hepatitis, malnutrition, infections, total parenteral nutrition. (3)

On the other hand we must take into consideration that the hepatic affection during the cytostatic treatment can be owed not only to it but also to other treatments that these patients benefit of: antibiotherapy, analgesics, antithermics, and so on (3, 6, 7).

Many of the chemotherapies can lead to hepatotoxicity, having an idiosincrasis action, due to the immunologic mechanisms or due to the variation of the host's metabolic response. These reactions do not typically depend on the dose. Less common, hepatotoxicity depends on the dose. Pre-existant hepatic disease leads to a more reduced toxins elimination and later it determines hepatic lesions up to cronic hepatitis and cirrhosis. (3, 8, 9)

The hepatotoxicity diagnosis is sometimes difficult, because the drug toxicity can mime any other hepatic disease. The estimation of the hepatic function and the hepatic injuries is indirectly made, the recognition of the hepatic injury sometimes being doubtful. There are no specific hystological or biochemical characteristics of a hepatic affection induced by drugs, and in many cases there are not simple and sure methods for the etiologic diagnosis. (3)

Hepatotoxicity **clinically** develops through *hepatic* disorder – signs and symptoms specific to hepatitis (fatigue, anorexia, nausea and increased transaminasis, sometimes asymptomatic, just the transaminasis being increased), *cholestatic manifestations* (jaundice, pruritus, the increase of alkaline phosphatase and a medium increase of the transaminasis), *mixed hepatic and cholestatic manifestations* and also shapes with *systematic affection* (fevre, Stevens-Johnson syndrom, renal dysfunction, myocardial disorder). (10)

The antineoplasis drugs used in the malignant treatments are divided in: alkilant agents (mechlorethamine, cyclophosphamide, ifosfamide, melphalan and chlorambucil), nitrozoureas (carmustine (BCNU), lomustine (CCNU) and streptozotocin), antimetabolites (currently in clinical use include cytosine arabinoside (ara-C), 5-fluorouracil (5-FU), 6-mercaptopurine, azathioprine, 6-thioguanine, methotrexate and gemcitabine), antitumours antibiotics (doxorubicin, daunorubicin, mitoxantrone, bleomycin, mitomycin, mithramycin (plicamycin) and dactinomycin), spindle inhibitors, topoisomerase inhibitors, platinums, interferon, and so on. In Chart no. I we mention the drugs more frequent associated with toxicity upon liver and the main consequences of hepatotoxicity. (3, 11-18)

The combined chemotherapy produces a higher hepatotoxicity by intensifying the effects thus determining changes from simply increasing the transaminasis, bilirubin, alkaline phosphatases to hepatic colestasis, hepatocellular necrosis, hepatic regenerative nodullary hyperplasia (combination of busulfan with 6-tiogunin), hepatic vein-oclusive disease, toxic hepatitis, hepatic cirrhosis and also hyperamoniemia. (3, 19, 20)

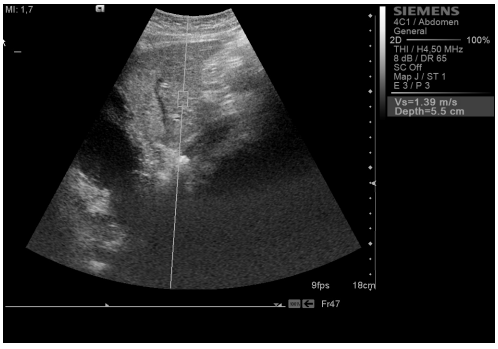

Fig. 2. Elastography of the left liver lobe to on obese girl (personal collection)

MATERIAL AND METHOD

The international criteria for asessing the hepatic toxicity according to the national Institute of Cancer includes the bilirubin, the transaminasis, GGT, FA, albumin, the flow on the vein (3).

Starting with the international studies (3, 6, 7) and those of our clinic on a number of 78 patients with different malignities treated with different treatment schedules including more cytostatics (1), it has been noticed that these biochemical parameters are not enough for the right assesssment of the chemotherapics' hepatotoxicity. Thus it is required the abdominal ultrasonography and computerised tomography, which are necessary for the identification of billiary tract, vascular system, tumoral associated conditions and the degree of fibrosis associated to the therapy. We mention that the hepatic biopsy may be necessary in order to appreciate the degree of hepatotoxicity. (3)

The ultrasonography examination which has a special place, is a noninvasive method for investigation, unpainful, repetitive and which allows a good exploration of the tissues and organs, in adults and children too.

The manual palpation was used a long time ago too in order to offer a qualitative evaluation of the tissues' stiffness. The need of a direct image led to the development of the imagistic methods ; "the palpation" through ultrasound (ultrasonography) is used for a longer period and the evolution of the technique concomitant to the increase of the necessity for the quantification of the pathological changes connected to the presence of an abnormal tissue, compared to the surrounding tissues (21) it led to the development of the ultrasonographic elastography.

The ultrasound **elastography** reffers to ultrasound methods which can produce images or measurement of tissue elasticity - the ability to resist to deformation, the application of tissue deformation on its strengths. The force applied to the tissue can be (22) the force applied by the ecografist's hand, the force applied by an external mechanical device, the force given by the physiological movements of the human body - breath, the cardiac activity, pulsed movements of large arteries or the force applied by a certain ultrasound issued by the ultrasound probe which makes the exploration itself**.** The response to the application of this force will vary according to the tissue elasticity.

This new method of diagnosis gives information related to the elasticity/stiffness of the examined tissue, degree of tissue fibrosis (eg. pre-stage liver cirrhosis), respectively the degree of stiffness of a tumor tissue compared to the free one, with promising results to differentiate between benign and malignant lesions or in assessing the

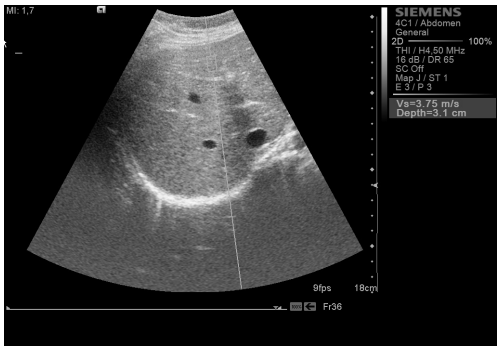

Fig. 3. Real time elastography to a child with three degree of fibrosis (personal collection)

tissue changes over time. (22)

There are different mechanisms of producing acoustic radiations and a lot of biomedical applications, especially in medicine, as diagnosis methods, in ultrasounds domain. (23)

The electromagnetic waves and the acoustic ones are capable to exert an equilibrum force called radiation force, this being a universal phenomina at any moving wave. A major interest in different biomedical applications of the acoustic force of radiation started in 1990 and it still works nowadays ; thus new applications have appeared, including the evaluation of viscous-elastic properties of the fluids and of the biological tissues, the imagery of the elasticity, molecular imagery and others. (24)

ARFI – "acustic radiation force imaging" (the diffusion impulse of the acoustic force) beside the elastography through compression "***eSie touch*** elasticity imaging" is a method which analyses the tissue area through ultrasound elastography. **ARFI** consist in generating an acoustic impulse in the tissue in order to assess/ interogate the mechanical properties of the tissue stiffness/ elasticity. The method has 2 possibilities of evaluation :

- ***Virtual touch tissue imaging*** – a method through which a diagram of the tissue stiffness is obtained, with a gray scale (reverse as the classical examination 2D) ;
- ***Virtual touch tissue quantification*** through which it is appreciated the speed of the transverse propagation of the waves triggered, allowing the quantification of the tissue elasticity.

The elastography methods previously available needed a manual compression of the tissue, an approach which could limit the depth of the image location and which could favour the appearance of artefacts. The ARFI method does not impose a certain degree of compression on the tissue, done by the examiner and which can vary (by hand fatigue), but it takes over the patient's respiratory movements, which means rhythmic and constant. The elastography using compression can assess just the superficial tissues, but with the ARFI method the tissue elasticity can be assessed starting with a depth of 1,5 cm up to 8 cm.

Unlike the conventional sonography B-mode which gives us anatomical details based on differences in the acustic impedance, the Virtual Touch image describes properties reffering to the tissue stiffness. In this respect, the Virtual Touch image is closer to a tissue evaluation through a physical palpation than through the conventional ultrasound.

ARFI technology is more and more studied in order to be used in different clinic application, including breast, liver, kidney, colon and rect tumours, the characterization of atheroscerosis plates, and also monitoring the ablation through radiofrequency. (25-31)

ARFI technology involves a mechanical compression of the tissue using acoustic impulses for a short time (pushing impulses), in a region of interest chosen by the examiner, which produces shear waves which spread from the interest area, perpendiculary on the acoustic impulse, generating localized displacements in the tissue, with a size of few microns. (32, 33) In the same time, detecting waves are generated of smaller intensity than the pushing impulse (1 : 100).

The moment of interraction between the shear waves and the detecting waves mark a short period between the shear waves and the crossing of the region of interest by this one. (34)

RESULTS

Registering the position of the shear waves in many locations and correlating these measurements with the short time, the speed of the shear wave can be quantified (shear wave velocity - SWV) (m/s), generally, the stiffer the region of the tissue is, the greater is the speed of the shear wave which passes through that region (fig. 1). Thus, the measured SWV is an intrinsic feature measured by an intrinsic and reproducible feature of the tissue. (35-37) The equipment measures SWV and the depth when the measurement was done too. Only one transductor (a diagnosis scanner) is used to generate the radiant force and to follow the displacement generated in the tissue.

Having in view the fact that technology is applied through software algoritms suplementary for control and imagary detection, the method can parallely offer a B-mode recording, color Doppler and ARFI images. (29)

Concerning the evaluation of difuse hepathopaty, there are a lot of studies, now being available preliminary results which were communicated at different conferences. (38 - 40)

The new ultrasonographic method of ARFI elastography allows valid, accurate and flexible evaluation of liver stiffness. Elastography of the left liver lobe is also possible which may be especially helpful in obese patients (fig. 2) (33, 41)

Thus the studies made by Sporea and the contributors who have quantified the speed of the contractual wave through ARFI method of the elastography showed, at healthy subjects, values of 1,24 $\pm$ 0,5 m/s, with values smaller than for the female gender (1,01 $\pm$ 0,15 m/s) and values higher than for the male gender (1,63 $\pm$ 0,59 m/s) and a little bit smaller in the younger subjects (0,93 $\pm$ 0,12 m/s in 18 – 29 years) compared to the oldest 1,55 $\pm$ 0,04 m/s for the group aged 50 – 59 years). (42)

ARFI allows SWV quantification of the shear wave velocity in strong correlation with the fibrosis stage. Steatosis does not influence SWV. (32, 33) The maximal performance of the method consists of the prediction in severe fibrosis and cirrhosis. The diagnostic accuracy is strongly comparable to transient elastography (Transient elastography, Fibroscan, EchoSens) only for the prediction of severe fibrosis and cirrhosis (for lower degrees of fibrosis, TE has better performances). (43)

Thus the studies made on adults' groups with chronic hepatitis found out the following values of the speed of the (42) shear waves for different stages of hepatic fibrosis: F 0: 1,31 $\pm$ 0,48 m/s; F 1: 1,52 $\pm$ 1,02 m/s; F 2: 1,61 $\pm$ 0,68 m/s; F 3: 1,76 $\pm$ 0,76 m/s; F 4: 2,81 $\pm$ 0,71 m/s (fig. 3).

ARFI method (the same with TE) has excelent predictive values for the presence of cirrhosis too. (20) The medium values of the speed of the shear waves in patients with compensated cirrhosis (Child A) are smaller (2,67 $\pm$ 0,73 m/s) beside the patients with decompensated cirrhosis. (Child B, C) 3,05 $\pm$ 0,8 m/s. (42)

Recent data show that the imagery through ARFI technology is a promising method based on ultrasounds for the evaluation of hepatic fibrosis in viral chronic hepatitis with a diagnosis accuracy similar to TE. (14, 44)

Elastography through ARFI method has a very good precision in the evaluation of the liver fibrosis and is superior to other noninvasive methods (APRI Index, FibroMax) in order to stage the hepatic fibrosis. (45, 46)

Elastography through ARFI method showed a good diagnosis performance than the visual evaluation by the radiologists

with experience in diagnosing the chronic hepatic diseases, and also the evaluation of their severity (it better correlates with the Child-Pugh scores and the tests of the hepatic functions, compared to an ultrasonography system of scoring based on the visual evaluation of the conventional ultrasonographic images in B- mode). (47)

CONCLUSION

The hepatic toxicity is discovered as routine by altering the hepatic biochemical tests, through the appearance of some symptomes characteristic for hepatitis, but the differentiation of hepatitis from hepatic cirrhossis and the right appreciation of the degree of the hepatic cirrhossis, useful for the therapy, can be obtained just through hepatic biopsy or by assessing the hepatic elasticity through so called "noninvasive biopsy" through elastography.

Thus, real-time elastography is useful and good in assessing the chemotherapics hepatotoxicity in children with cancer, which in future will get into a schedule of monitoring these children.

MANAGEMENT OF EISENMENGER SYNDROME IN A LATE PRESENTATION OF TRANSPOSITION OF THE GREAT ARTERIES ASSOCIATED WITH INCIDENTAL ADRENAL TUMOR. CASE REPORT (Abstract): We present the case of a 25-year-old patient with transposition of the great arteries (TGA), ventricular septal defect (VSD), without surgical correction, severe pulmonary hypertension and Eisenmenger syndrome, under vasodilatation therapy with Bosentan and Sildenafil, which presented for hemoptysis, shortness of breath at mild effort, myalgia, headaches and vertigo. Blood test showed important erythrocytosis and thrombocytopenia. CT examination revealed the presence of an adrenal incidentaloma (AI), which was proved to be nonfunctional after hormonal testing. Management of the patient included phlebotomy for the treatment of the hyper viscosity syndrome and recommending the addition of a prostacyclin analogue to the vasodilators scheme. The dimensions of the AI raised the question regarding the need of surgical excision, due to the risk of being an adrenal gland carcinoma. Due to the high risk of general anesthesia in Eisenmenger patients, a multidisciplinary team (endocrinologist, cardiologist, surgeon, and anesthesiologist) decided on a watch and wait strategy regarding the tumor, with regular monitoring. **Keywords:** TRANSPOSITION OF THE GREAT ARTERIES, EISENMENGER SYNDROME, PULMONARY HYPERTENSION, ADRENAL INCIDENTALOMA

Transposition of the great arteries (TGA) is the 2nd most frequent cyanotic congenital heart disease (CHD), after tetralogy of Fallot, with an incidence of 20-30/100,000 births and represents 5-7% of all CHD (1). Also, it is the most common CHD in the neonatal period, being responsible for 25% of the deaths caused by CHD in the first year of life. If it is associated with other congenital malformations which create a communication between the 2 circulatory systems, such as ventricular septal defect (VSD), the survival rate can be up to 50% in the first 3 years (1). However, these patients develop severe pulmonary arterial hypertension and Eisenmenger syndrome (ES) in the first year of life, therefore the survival till adulthood is uncommon without surgical interventions for correction or palliation.
